Altho Dramatic Compositions in every Language are the most difficult, yet I do not find this Author (*Sophocles*) so troublesome as I expected.

Later he says:

I finished yesterday the Plays of *Sophocles*.

On November 14th, 1779, he declares:

I at least can say that I write Latin at present more easily than formerly.

About this time, being already a Glasgow exhibitor, he asks his uncle and guardian to help in procuring for him another small exhibition. He obtains Bishop Warner's exhibition in succession to a Mr. Hadow (a family name

still well known in the university), and thanks William Hunter for applying for it in his behalf:

If my other qualifications should be mean I hope at least it shall never be said I have been deficient in gratitude.

The small exhibition is "a very necessary addition in so expensive a place as Oxford." The letter is signed, "Yours most affectionately."

In 1780, when still only a lad of 18, he reads the plays of Sophocles a second time between New Year's Day and February 17th. He notes that the choruses are obscure. At the same time he despairs of ever writing Latin as purely and with as much facility as English. His taste is evidently improving, and he has travelled a long distance since he wrote from Glasgow to his uncle about the neglect of scansion prevalent in the North—a neglect that must have made nonsense of Virgil to a Scottish student. He wrote:

Quantity is still shamefully neglected in Scotland. We scarce know what is meant by Quantity. Since you have wrote me, I have been paying attention to it, and yet after all I shall be found very deficient.

At Oxford he made up for all deficiencies, and got through a prodigious amount of classical study, having, as he himself states, read Caesar, Livy, Cicero's *Tusculan Disputations* and *The Offices*, Terence (the Latinity of this author being found impure), Tacitus, Seneca, eleven books of the *Odyssey*, Plato's *Dialogues*, Xenophon's *Anabasis* (much admired by him), Demosthenes, selected orations of Aeschines, and, as before mentioned, Sophocles (twice), besides translating into English and then retranslating into Latin five or six books of Caesar and the *Tusculan Disputations*.

All this time he was bent on becoming a physician, and, indeed, studied hard under William Hunter in his vacations, thus laying the foundation in his Oxford days of his unrivalled anatomical knowledge.

Matthew Baillie's own account of his early education is contained in an unpublished memoir of his life, written "with a view of furnishing authentic materials." It is interesting as throwing light on the excellence of education in the Scotland of the eighteenth century and on the boyish ideals and experiences of a learned physician of the past. Dr. Baillie writes as follows:

I went to the English School at Hamilton when I was not quite five years old, and remained there till I was near seven. The schoolmaster's name was Allen, a most respectable man, and he was married to a sister of my Father. I was taught writing and arithmetic by Mr. Telfair, who succeeded Mr. Allen after his decease. I went to the Latin School at Hamilton before I was quite seven years old, and remained there six years. The Master of the School was named Whale. He was a man of quick parts, of various knowledge, and with a considerable turn for humour. He was an excellent Latin scholar, but was not very thoroughly acquainted with the Greek, altho' he had enough of the latter language for the creditable teaching of his school. I was there taught both Latin and Greek, and was considered as a good scholar. I was most commonly at the head of my class, but this arose entirely out of my emulation and industry. There were several Boys in the School of better Parts than myself, but they had less diligence. When I left the school in the afternoon, and went to my Father's house, the first thing I did was to prepare myself for the lessons of the next day. When this was done, I played with all the wildness and spirits of Boys at that early age.

Before I had quite completed my 13th year I left school and became a Student at the University of Glasgow. I first entered the Latin and Greek Classes, and went through a full system of classical and Philosophical education there in the course of five Sessions. The Professors in these various departments were men of considerable eminence, were exceedingly attentive to their duties, and had the power of exciting great emulation among the students. I still maintained the same character among the students which I had done at school, and chiefly from my industry and emulation. I had it likewise very early and very frequently impressed upon my mind by my Father, that my chance of future success in life depended entirely upon my industry and good character. In the year 1779, when I had not completed my 18th year, I was appointed to an Exhibition in Balliol College Oxford by the Professors of Glasgow, and in April of that year came up to England. I thence waited immediately on my arrival upon Dr. Hunter my Mother's Brother in Great Windmill Street, who received me kindly, and I staid with him about ten days before I went to Oxford. He was the Relation who had it most in his power to be useful to me with regard to my future prospects, and this determined me to enter into the medical Profession. I had no strong liking for this Profession, as happens to some individuals, but I had no dislike to it, and I entered upon it willingly. At this time too I waited upon Mr. and Mrs. Hunter,

and they received me kindly, altho' there was a disagreement between Him and his Brother Dr. Hunter. After being ten days in London I went to Oxford and remained there nearly eighteen months without interruption. I had the advantage of a very good Tutor, the Revd. Mr. Prosser, now the Revd. Dr. Prosser, a Prebendary of Durham, and improved myself considerably in the Classics, more especially the Greek, and acquired by reading some general knowledge. At that time Science was very little cultivated at Oxford, and I gained little in addition to what I had brought with me from Glasgow.

He studied mathematics, however, to some purpose while at college, though he does not tell us to what point. In 1780 his medical studies began in London, but he continued to keep his terms in Oxford. It is not our purpose to describe Matthew Baillie's medical education here, as that is sufficiently recorded by Wardrop, his biographer. He found William Hunter "mild and kind," never "familiar and warm," though he enjoyed his confidence to such an extent that he became chief teacher in his Windmill Street dissecting-room in 1781. Of William Hunter as a teacher he says:

He excelled very much every Lecturer whom I ever heard, in the clearness of his arrangement, the aptness of his illustrations, and the elegance of his diction. He was probably the best Teacher of Anatomy that ever lived.

V. G. P.

THE BRITISH MEDICAL BENEVOLENT FUND.

A MEETING in support of the British Medical Benevolent Fund was held in the Library of the Royal College of Physicians, London, on Tuesday, with Sir JOHN TWEEDY, President of the Fund, in the chair.

Dr. SAMUEL WEST (Treasurer) said that the Fund was founded in 1836, and during the past seventy-three years had expended over £70,000 in grants, and rather more than that amount in annuities. The object of the Fund was the relief of medical men and their families in severe and urgent distress. The only qualification to benefit by the Fund was poverty and distress. Temporary distress was relieved by grants of money, and permanent ill health or old age was relieved by annuities. The value of the annuities was from £20 to £25. The grants of money varied from £5 to £20, and last year over £2,000 was distributed in that manner. The Fund stood as a bulwark between the benevolent public and the begging-letter writer and other impostors.

The BISHOP OF OXFORD (Dr. Paget) said that the Fund made provision by pension and by grants for medical men who had fallen into poverty by no fault of their own, or for the wives and children of medical men when left in poverty. There was no profession in which a man was so much compelled without any choice of his own, without any chance of escape, to run such great risks of unavoidable impoverishment involving himself and his family. In most cases, when a student came to the end of his education for the medical profession, when he was qualified to seek for practice and hoped to earn a living, he had spent a very large sum of money and had drawn all that he could from his home. In other words, most medical men by the time they qualified for practice had fairly well exhausted their capital. From the very first the medical man had to meet expensive demands. It was appalling to think what was required of a medical man in the way of keeping up appearances. He must not only have a house, but it must be of a considerable size and in a good position. Then there was the necessity of spending a good deal of money on clothes. He was expected to show a sort of chastened expensiveness in his attire, a kind of sober and unostentatious dignity in his apparel. He was not required to be smart, but the medical man must certainly not be casual or indifferent in his dress. Altogether he must incur a considerable outlay long before he could hope to begin to earn anything at all. Then he must have a carriage or a motor, for a medical man who proposed to see his patients without would find them very few. It was also generally expected of a medical man, and wisely so, that he should be married, and thus he incurred quite early in his career a very considerable burden of anxiety and expense. It was of the utmost importance that the medical man should have the health to support that burden of anxiety for many years so as to be ultimately rid of pecuniary embarrassment, for a doctor was lucky if he was quit of debt by the time he was

forty years of age. Everything, then, depended on his health and ability to stand hard work. They were his one asset without which theory, education, ability, skill, and recommendations were useless. The medical man therefore risked his all upon his health, and his health was exposed to extraordinary risks, considering the load of anxiety under which he worked. His time for sleep and his time for meals was uncertain. He had to risk exposure to all sorts of weather at all times of the day and night; he could never be sure of a spell of rest for many years, and he hardly ever got a holiday. He was constantly exposed to the risk of infection from fever and blood poisoning. Therefore he was risking his health all his life, and he was doing this under very real conditions of difficulty and strain, so that the medical man's hold upon health and power of work was secured to him by the most precarious tenure. It must be remembered also that health meant more to a medical man than to most men, for the public preferred to employ a doctor who was himself well and strong. It was a disastrous matter for a medical man to have a long illness, and it was disheartening for him after a protracted spell of ill-health to take up his practice again, for often it would be found that his practice had more or less left him. The public turned to those medical men of whose stability of health and readiness for work they could be assured, and it was pathetic to think how often a man struggled through a convalescence from illness, only to find that it would take him months or years to recover lost ground. That great asset of health on which a medical man staked his all was of such a precarious nature that the need for the British Medical Fund was clearly indicated. Another method of understanding the urgent necessity of this Fund was by looking through the list of the cases relieved. The want which was relieved by the annuities given by the Fund was urgently pathetic, but behind that list of annuities there were a great many deserving cases for which no money at all could be provided. When it was remembered that the subscriptions for the year were unfortunately not enough to warrant any grant at all in a large number of necessitous and deserving cases, then it was recognized what a great need there was for the encouragement of this Fund. His father, Sir James Paget, lived and worked under the full stress and strain of those risks which had been described. Sir James Paget through all his early professional life was burdened with debt, mostly not his own, and he was, moreover, in most precarious health; at first he did not and could not save anything at all. Speaking of the risks which a professional life such as that of Sir James Paget involved, he doubted whether, could they have been foreseen, any prudent man would have incurred them. It might be summed up in the fact that if Sir James Paget had died before he was 47 he would have left his wife and children in extreme poverty, for before that time he had not been able to save a shilling, and the largest life insurance he could have afforded would have been quite insufficient for bringing up his children. The Bishop concluded his appeal by saying that when he thought of the gallant courage shown by his father in his work, of his uncomplaining fortitude, of his ceaseless and invincible diligence in his professional labours, of his daily cheerfulness, and of the patience with which he bore the risks described, he did not doubt that he would be successful in pleading for the Fund which was devoted to the benefit of medical men.

THE LORD MAYOR OF LONDON said that he had always felt the highest admiration for the medical profession and for its self-denying devotion to the service of the public. He referred, first, to the family practitioner, who was very often the sole friend and comfort in a bereaved household, and then referred to the successful work done by the Corporation of the City of London through its medical officers in preventing disease in the Port of London. The Corporation of the City of London was engaged in the prevention of the entrance of disease into this country. It was enabled to carry out this work successfully because the medical profession had worked for years in order to discover means for preventing the spread of disease. As the result of those labours its medical officers were able to stop the entrance of disease, and thus the city was saved from diseases which might decimate the population. It must be remembered also that the prevention of disease

was an excellent thing for the State, because health was considerably cheaper than disease. He considered that the State and the public had done very little in return for the benefits which the medical profession had conferred on the country, and it seemed to him that the public should be called to its duty in that respect, and he hoped that the Fund would benefit greatly as a result of the meeting.

SIR R. DOUGLAS POWELL suggested that if every member of the medical profession were to contribute even a small sum to the Fund it would have a great effect on its position, and that good effect would be increased if medical men interested their friends in the work of the Fund and recommended it to the notice of the charitable public.

SIR JOHN TWEEDY, in a few concluding remarks, pointed out the importance of what the Lord Mayor had said in regard to the economical value of the medical profession in preserving the health of the nation.

The business of the meeting terminated with a cordial vote of thanks to Sir John Tweedy for presiding.

THE UNIVERSITY OF BRISTOL.

THE EXPECTED CHARTER.

If rumour be true the charter for the new University of Bristol will be granted by the Privy Council before Easter, and the university will come into being before the new year. The Committee that has worked so long and so hard for this object may well congratulate itself on reaching the goal that it had in view, for it is only a little over thirty years since the University College was opened, and but one since the first prospectus and list of donations towards the university was published.

THE MEDICAL SCHOOL.

It will be of interest to pass rapidly through the successive stages since the germ of the university first started into activity. It may be claimed, without fear of contradiction, that the first step towards the goal now so nearly won was the foundation of the medical school in the year 1814, or perhaps, to be more correct, the course of lectures given by Dr. J. C. Prichard, Mr. Bowles, and Mr. Shute at the Royal Infirmary in that year. In 1818 these lectures were recognized by the London authorities, and the first prospectus of the Bristol Medical School followed in 1832. Since that time to the present—for the school was affiliated to the college in 1893, and made a faculty in 1907—a regular course of medical instruction has been carried out; and though the lecturers had little to do with the foundation of the college, it was due to the needs of that school and the desire to have the means of higher education, that the idea occurred to others that a university college was required. To complete the history of the connexion of the medical school with the college, it may be added that after being housed for some years in King Square it was moved to Old Park, and from that site to the present buildings now part of the college.

THE UNIVERSITY COLLEGE.

According to Latimer, the author of *The Annals of Bristol*, it was in the spring of 1873 that a proposal was made to found a technical college of science, of which the medical school was to form a part, and an appeal was made for subscriptions to carry out this idea. The chief promoter of this scheme was the present Bishop of Hereford (then head master of Clifton College), and he was strongly supported by Professor Jowett, Dr. Temple (then Bishop of Exeter), Sir Henry Roscoe, and Mr. E. A. Freeman. As a result, the University College was started in the autumn of the same year, with a staff of two professors and four lecturers, being housed in a temporary premises in Park Row, a building now occupied by the South Midland Royal Engineers.

From the first the history of the college has been one of continued success; a very large number of students have passed through it, and it was found necessary at different times to increase the staff and enlarge the buildings, till at the present time there are nine professors, one assistant professor, twenty-four lecturers, and three readers in the

Faculty of Arts and Science, and eight professors and twenty-one lecturers in the Faculty of Medicine.

The available space in the building in Park Row soon became exhausted, and a move was made to the present site, where a building valued at £45,000 was erected.

THE PROPOSAL FOR A UNIVERSITY.

Though the college has always proved a great success, it was soon felt that the educational equipment of the city would not be complete till it could grant its own degrees and provide a place and afford facilities where original work could be carried out. Further, it was felt that if a high standard of work was to be aimed at it was essential that those who gave their time to instructing others should be well paid, for it would be impossible to command the services of the best teachers if the emoluments were insufficient to attract and to retain the best men. For this a considerable endowment would be required, and it was with this object in view that a movement was made by certain prominent citizens in 1907 to start a fund for the endowment of a university. Following the example of some of the recently created universities of the North of England, a sum of a quarter of a million was asked for, and the recent gift of Lord Winterstoke of £15,000 about completes that sum.

Some years ago there was started to assist the college in its financial needs a society known as the University College Colston Society. It was founded on much the same plan as the well-known political societies which bear the name of the great Bristol philanthropist—that is to say, an annual dinner, a subscription list, and a speech by some person distinguished, in the case of the college, not in the political but in the educational world. The idea originated with Mr. W. Reid, the proprietor of one of the Bristol papers, who pointed out that more than half of Colston's gifts to the city were for educational purposes, and that the citizens of Bristol would be carrying out the objects and aims of Colston if they helped towards the higher educational movement of the present day. For some years this society has met annually, and the dinner and the donations have both helped in their way to advance the college. But of all the meetings, that which will be longest remembered was the meeting of January 14th, 1908, for it was then the proud privilege of the president, Mr. G. A. Wills, a member of the well-known Bristol family, to announce that his father had given the sum of £100,000 to the university fund, and by this magnificent gift had assured the existence of the Bristol University. Mr. Henry Overton Wills, the gentleman who has given this sum, has not lived in Bristol for some years, but his name will always be remembered as the founder of the university.

This magnificent gift of Mr. H. O. Wills overshadows the donations of others, but a large number of wealthy persons in the city have given handsomely, so that as mentioned before the sum of about £250,000 is now in hand for building and endowment.

It would be invidious to mention the names of only a few of the many who have worked so hard for the university, for some one might be omitted; but a notice such as this, which is intended to be a short record of the many steps that have been taken, would be very imperfect if no reference were made to Mr. Albert Fry, who unfortunately died before he saw the fulfilment of his hopes, to the Bishop of Hereford, the Bishop of Bristol, and the Right Hon. Lewis Fry. There are many more, and only space prevents their mention.

THE MERCHANT VENTURERS' COLLEGE.

But unfortunately there have been difficulties in the path, and these are not even now removed. It was hoped that it would be possible to come to some agreement with a technical college that has for many years been in existence in Bristol known as the Merchant Venturers' Technical College. This institution had its origin in a school founded in March, 1856, under the title of the Bristol Trade and Mining School, and was taken over by the Society of Merchant Venturers in 1885. At first it was known as a school, but to bring it into line with like institutions in other towns the name was changed to college. The society that owns the college is the last surviving of the old trade guilds of Bristol, and, like some of these in London, has made use of its surplus funds to further

education. The foundation of this college was at the time of its opening commented on by a prominent citizen who expressed a regret universally felt that "while we have a grammar school and a university college, both admirably officered and doing good work, but sadly hindered by lack of funds, we see a gigantic trade school arising to be a rival to both of them." This has unfortunately proved only too true. When the university scheme was started it was hoped that some support would be granted by the city out of the rates and this has been promised, but only on condition that some working agreement is come to between the two bodies. Negotiations have been going on now for a very long time, and it is hoped that an agreement may be come to. If report be true the university committee have come to an end of their patience, and it is hoped that the Privy Council will grant the Charter in spite of the fact that the Merchant Venturers will not join in the university. It is possible that the question of the rate may be got over, but a very practical solution of the difficulty would be for the university to be independent by raising another £100,000 which would put it in a better position though not as good a one as if helped by a rate.

THE AIMS OF THE UNIVERSITY.

The Draft Charter was laid on the table of both Houses of Parliament last autumn, and for the due time. It is now before the Privy Council, and only requires to be laid before the King to receive confirmation.

This account would not be complete without some reference to the aims of those who are promoting the university. Hitherto the students have been trained and instructed mainly for the University of London, and, in the case of the medical students, for the Conjoint Board as well. It is hoped soon that there will be a complete system of examinations as well as instruction for degrees granted by the University of Bristol, and it is quite certain that the standard of work required will not fall below that of either the older or of the more recently formed universities. Bristol, with the magnificent endowment obtained, will be able to offer as good an education and at as reasonable a cost to parents as any in the United Kingdom, while it is intended that the degrees shall rank as high. It is further hoped that by awarding bursaries and scholarships to deserving students that original work of a high order may be carried on within its walls which will bring renown to the university and to the city.

The present building will, of course, have to be much enlarged, and the committee were very fortunate in being able to purchase the buildings of the Blind Asylum. This will give the university a fine frontage on the main road, though the present building will have to be replaced by a more suitable one. No plans are at present published, and, indeed, it would be premature to do so, for until the charter is actually in the hands of the committee no steps can be taken.

LITERARY NOTES.

We have received the first copy of *National Health*, a magazine which appeals to all interested in questions of public health. It is the official organ of the Women Sanitary Inspectors' Association, the Children's Protection League, and the Women's National Health Association of Great Britain. Among the contents of the first number is an article on the Children's Protection League, by Lord Monkswell. Mr. Henry Curtis, F.R.C.S., contributes a paper on rickets; Dr. A. Nimmo Walker discusses the Midwives Act in its relation to the blindness of infants; Dr. O. E. Starr, L.D.S., discusses the question of the care of the teeth; Dr. Elizabeth Knight writes on the social and sanitary conditions of prison life. There are also articles on the passing of the woman sanitary inspector, a second-grade nurse, and the medical inspection of school children, with reports, editorial reflections, and other matter. The editorial offices are at the rooms of the Medical Society, 11, Chandos Street, Cavendish Square, W.

Among the books in Messrs. Methuen and Co.'s New Announcement List, an early copy of which we have received, is one entitled *Drugs and the Drug Habit: Chapters on the Dynamics of a Remedial Particle*, by Dr. Harrington Sainsbury, Senior Physician to the Royal Free Hospital. The purpose of the work is said to be to point out the precise relation in which the medicament stands to

disease, and how it is fitted to solve the problem, physical and psychic, which the malady sets; to claim for the drug its position as a natural force obedient to natural laws, and to show how impossible it is to separate it, including its latest congener the *serum*, from other classes of natural products; to make prominent the fact that drug habits are but instances of a law fundamental throughout nature, and to discuss the broad lines upon which prevention and cure should proceed in the treatment of habit; in brief, to naturalize the drug both in its use and abuse.

Messrs. Bale, Sons, and Danielsson, Limited, will shortly issue a History of the Reading Pathological Society, written by the President, Dr. Jamieson B. Hurry. This society ranks as one of the oldest medical societies in the country. The good work it has done is shown by the numerous original communications which have been published during the past seventy years, to which full references will be given. The volume will be illustrated by a series of portraits, and contain descriptions of the medical library and pathological museum, which form so essential a part of every progressive medical society.

Mr. Alston Rivers will publish at once a volume entitled *Labour and Housing at Port Sunlight*, by W. L. George, author of *France in the 20th Century*, who has made a careful survey of the first attempt at a model village. Though his opinion on the whole is favourable, he freely criticizes the system.

We had not intended to say anything further on the subject of Esperanto at present, but we have received a letter from Dr. G. S. Robinson of Eastbourne which courtesy compels us to notice. Referring to the statement which we quoted from Mr. Remy de Gourmont as to a friend who asked "what mental aberration had led Esperantists to use *viol* (rape) to denote a *violet*," Dr. Robinson says: "The answer, of course, is that *violet* is the Latin for a violet, and (as with most scientific terms), the Esperanto equivalent, '*volo*'—not '*viol*,' by the way—is taken direct from that language as a common source. The Latin, English, and French languages all use the root-word '*viol*' for both '*a violet*' and '*to violate*'; but Esperanto never uses the same root-word for two different meanings, and so prevents any possible confusion." *Volo*, on the whole, strikes us as a more infelicitous name for the proverbially modest flower than *violet*. But on looking at the vocabulary in *Esperanto Self Taught*, by Mr. William W. Mann (London: E. Marlborough and Co.), we find at p. 17 *violeto* given as the Esperanto equivalent for violet. The book bears what may be taken as the imprimatur of Dr. Zamenhof, the founder of Esperanto; it may, therefore, be assumed that it contains no error. There is evidently some difference of opinion among Esperantists about the proper form of the word. *Non nostrum tantas componere lites*. The fact, however, serves to illustrate our remarks as to the inevitable mutations that must take place in Esperanto as in languages developed by the natural process.

Contract Practice.

PROPOSED FEDERATED SOCIETIES' MEDICAL BENEFIT ASSOCIATION.

THE following circular has recently been issued, and it will be noticed that the promoters of this new organization hope that the scheme may be in working order at the beginning of next April. It will be observed that it is intended to apply to members of dividing friendly societies who live outside the radius of their own society's doctor and have hitherto been unable to take advantage of the facilities for medical benefit at the cheap rate provided by the societies.

FEDERATED SOCIETIES' MEDICAL BENEFIT ASSOCIATION IN CONNECTION WITH THE NATIONAL FEDERATION OF DIVIDING FRIENDLY SOCIETIES,

7, COLEBROOKE ROW, N.

At the 1908 Conference a general desire was expressed that the Federation should do something to place facilities for Medical Benefit at a cheap rate within the reach of those members who, by reason of living outside the radius of their own Society's doctor, were debarred from such benefit. At the same time it was made clear that no scheme that involved Secretaries in additional work, or which interfered in any way with the funds of individual Societies would be generally acceptable.

The Federation Executive now have the pleasure to announce that they have adopted a scheme which, whilst giving members, in whatever part of Greater London they may reside, the services

of a local medical man at the same rate as that usually paid in London societies, does not interfere in the smallest degree with the funds of individual Societies nor put upon local Secretaries any additional work of any kind. The scheme will be worked under the name of the "Federated Societies' Medical Benefit Association," and will be managed by a committee of five members appointed by the Executive. The Association will select about 100 doctors, in different localities, and publish their names on a suitable display card, which Societies may exhibit in their meeting rooms. It will then be open for members of Affiliated Societies to choose any name from this list, and, on forwarding the name to the Federation Office, together with a quarter's subscription (1s. 1d.), they will receive in return a receipted membership card which will entitle them immediately to the services of the doctor whose name the member has chosen.

Many of the doctors whose names will appear on the published list have agreed, if their approval is first sought, to attend other persons in the member's family at the same rate of payment. With this extension it is hoped that the scheme will afford a wide scope of usefulness and place every Affiliated Society in London in a more advantageous position in respect to the facilities for medical benefit which it can offer its members than is at present possible with even the largest Dividing Societies in London.

The scheme is intended to meet the case of only those members who are unable to take advantage of the service of their own Society's doctor, and no Society agreeing to exhibit the Association's card need apprehend the scheme will interfere with the working of local Societies' own medical funds; and in order to make this further sure, the doctors whose names will appear on the Association's list will be found, in most cases, to be the doctors already acting for local Societies.

It is claimed for the scheme that it is simple and effectively meets the desired end whilst avoiding objections which were feared, and it is hoped to get it into working order by the beginning of April. Societies wishing to give their members the advantage of the scheme will be supplied with the Association's card (about 18 by 16 inches) for exhibition in their meeting rooms. This card will contain all necessary information, and members need only be referred thereto. Applications for cards should be sent to the Federation Office.

RULES.

1. Members of any affiliated Society may become members of the Association.
2. The contributions to the Association shall be 1s. 1d. per quarter payable in advance, by post. Two or more quarters may be paid at the same time, but in all cases this card must be sent for receipt to be acknowledged thereon, and a halfpenny stamped envelope enclosed for its return. No member shall be entitled to benefit during any period for which the contribution has not been paid.
3. For such payment the member shall be entitled to receive free medical attention and medicine (but not attention or appliances in surgical cases), and a certificate of inability to work where such, in the doctor's opinion, may be necessary, from the doctor whose name appears on the other side of this card.
4. Each member must observe his doctor's regulations as to surgery hours and the giving of notice for home visits; and this card must be produced at each visit to or from the doctor.
5. Members may change their doctor at the beginning of any quarter but not at any other time. Notice of any desired change must be sent with the contribution.
6. The Association shall be managed by a Committee appointed by the Executive of the National Federation of Dividing Friendly Societies and all funds shall be banked under the control of two trustees.

FRIENDLY SOCIETIES AND MEDICAL CONTRACT PRACTICE.

SIR,—It is pleasing to note that Dr. F. W. Styles's letter has created some stir in the profession, and still more so to know that Denbigh and Flint have taken some action. Would not the profession be better served by their Divisional representatives if such actions spread, instead of so much grumbling in the medical and lay press?

I venture to suggest that the action should be organized by the central governing body, and a big effort made to make it general throughout the land, as there must be a considerable amount of overlapping in practices on the border of two Divisions.

Further, I venture to suggest that the manner in which the parish appointment is worked is to some extent responsible for clubs, with low fees for women and children. The parish doctor finds it better to take a few shillings per annum than to be obliged to see the patient for nothing as a pauper. Why should a pauper be compelled to have his doctor chosen for him? The appointment should, to my mind, be open to all who care to put their names down for the work, and the pauper be given choice.

In a few hours a clerk could ascertain the amount of the parish pay earned by each doctor for the past year at the cost of a few shillings to the ratepayers.

One further grumble in conclusion. Why should a doctor who has an infectious case which cannot be conveniently isolated at home be compelled in many districts to hand his patient over to the medical officer of health at the isolation hospital?—I am, etc.,

January 18th.

GRUMBLER.

Medical News.

WE are requested to state that Dr. Phineas Abraham has resigned the post of Surgeon to the Hospital for Diseases of the Skin, Blackfriars.

DR. JAMES MENZIES of Worksop has, on the recommendation of the Duke of Portland, Lord-Lieutenant of the county, been appointed a Justice of the Peace for Nottinghamshire.

AT the meeting of the Society of Tropical Medicine and Hygiene, to be held at 11, Chandos Street, Cavendish Square, W., on Friday next, at 8.30 p.m., Dr. H. G. Waters will read a paper on a new pathogenic spirochaete associated with bronchitis and fever; and Dr. T. Fausset Macdonald will present a communication entitled *Tropical Notes from Barbados*.

A QUARTERLY meeting of the Medico-Psychological Association of Great Britain and Ireland will be held in the new medical schools, Cambridge, on Tuesday, February 23rd, at 3 p.m., under the presidency of Dr. Charles Mercier. Dr. H. B. Donkin will introduce a discussion on the certification of mental defectives as proposed by the report of the Royal Commission on the Control of the Feeble-Minded, and Dr. William Graham will read a paper on the modern movement of psychotherapy.

ZAMBACO PACHA, M.D., of Constantinople, has given £600 to the French Society of Dermatology and Syphilography for the foundation of a prize which is to bear his name. The prize will be awarded every two years to the author of the best work sent in dealing with a subject in the domain of dermatology or venereal diseases. The competition is open to all nationalities, but the essays must be written in French. The first award will be made in April, 1911. The essays must be in the hands of the general secretary on or before November 30th, 1910.

THE eleventh International Congress of Ophthalmology will be held at Naples in April next (2nd to 7th). We are asked to state that an effort is being made to arrange special terms for travelling expenses and hotel accommodation for those who may wish to attend the Congress. It is proposed to issue for perusal before the meeting the communications offered for discussion at Naples. These will be sent only to those who have signified their intention to be present, and have paid the congress subscription (25 francs for members, 10 francs for each accompanying member of a family). To facilitate these arrangements it is most desirable that those who wish to attend should make the earliest possible intimation to one of the corresponding members for Great Britain and Ireland—Mr. Walter H. Jessop, 73, Harley Street, London, W.; Dr. George Mackay, 20, Drumshugh Gardens, Edinburgh; or Sir Henry Swanzy, 25, Merrion Square, Dublin.

ON February 5th, at a meeting held at the Warneford Hospital, Leamington, Dr. Thursfield was presented with his portrait in oils by his colleagues on the staff and committee and other friends. The presentation was made by the Chairman of the Hospital Committee (Major Chesshyre Molyneux), who said that Dr. Thursfield was elected Honorary Physician in 1882 at the time when the hospital consisted simply of the old building and had no ground except that upon which it actually stood. Owing in a very great measure to Dr. Thursfield's energy, four new wards and a nurses' home had been built, while the hospital had acquired three acres of land giving plenty of light and air. In addition, Mrs. Thursfield had generously furnished and equipped two of the wards at her own expense. The portrait represents Dr. Thursfield in an M.D. gown, and is considered an excellent likeness.

THE London County Council at its meeting on February 2nd approved arrangements which the Education Committee have made with the Queen Victoria's Jubilee Institute of Nurses for the treatment in their own homes of children suffering from suppurating ears. It has been found in many cases that the usual treatment by syringing, requiring as it does time, care, and patience, is not carried out properly by the parents. A card will be sent to parents whose children are found by the school doctor to be suffering from the affection, telling them that a nurse will attend at the house and administer treatment after the child has been seen by a medical practitioner. On the back of the card is an order to be signed by the doctor requesting the nurse to "syringe the ears of the child twice daily for the next three weeks, using only warm boracic acid lotion, and afterwards drying out and insufflating a very little dry boracic powder." After thus arranging the doctor's prescription for him, the Council nevertheless adds: "It is to be distinctly understood that the nurse, if she attends your

child, will act under the instructions of the doctor of the hospital authorities as the case may be, and that the London County Council will accept no responsibility for the treatment prescribed or given."

THE third meeting of the Departmental Committee appointed by the Lord President of the Council to consider the working of the Midwives Act was held at the Privy Council Office on Thursday, February 4th. Mr. Almeric FitzRoy, C.V.O., was in the chair, and Miss Bertha M. Broadwood, Honorary Secretary and Director of the Cottage Benefit Nursing Association, and Miss Rosalind Paget, Honorary Treasurer of the Incorporated Midwives Institute, gave evidence on behalf of their respective institutions.

DR. BENJAFIELD is medical officer of health for the district of Glenorchy, in Tasmania, and his little pamphlet, *Health in the Orchard*, draws an idyllic picture of the place that may well tempt those who seek the simple life. Glenorchy, we are told, is a tract of land some 10 miles square, "dotted all over with cultivated gardens and orchards." There people "spend all day in the sunshine, pruning in winter, digging and ploughing in spring, weeding and spraying in big apple and pear orchards, picking small fruits in the early summer, and later on the hard fruits as they come in." No wonder many of them are still young at 85, and their death-rate is only 4 per 1,000. Incidentally, the Tasmanians are trying to place more of their fruit, and especially their pears, on the home market, and it is gratifying to learn that Dr. Benjafield has been a pioneer, not only in pear culture, but in solving the many problems connected with the packing and shipping of this delicate fruit. We hope to meet Dr. Benjafield's pears at many an English dessert in the near future.

At a recent meeting of the Child Study Society, when the chair was taken by Mr. C. McLaughlin Barlow, LL.D., member of the London County Council Education Committee, a discussion on the report of the Royal Commission on the Care and Control of the Feeble-minded was opened by Dr. Shuttleworth, who, while recognizing the extraordinary industry of the Royal Commissioners, ventured to criticize some of their recommendations. In the first place, he doubted whether it was advisable to "tar with the same brush" the adult lunatic and the simply abnormal—perhaps only subnormal—child, as was contemplated in Recommendation III (BRITISH MEDICAL JOURNAL, 1908, vol. ii, p. 416), which proposed that all persons of unsound mind, whether lunatic or idiot, as well as the "feeble-minded," should be legally included in the term "mentally defective," thus abolishing the distinction between mental derangement and original mental deficiency, which has important administrative as well as scientific bearings. He thought also that a too rigid requirement of notification and registration of young children found unfit for ordinary education, though capable of benefiting by special instruction, would defeat its own end by wounding the susceptibilities of parents and tend to prevent those of the well-to-do classes especially from seeking for such children appropriate training. Mrs. Burgwin, Superintendent of Special Instruction, London County Council, referred to the difficulty of exact and early diagnosis in the case of many younger children and to the disadvantage of divorcing from the scheme of elementary education, and transferring to an authority controlling adult lunacy the care of children of school age, whatever might be desirable after that age. Dr. Ettie Sayer, Assistant Medical Officer (Education), London County Council, urged that parental susceptibilities must be subordinated to the general social weal. Dr. Caldecott, Medical Superintendent, Earlswood Asylum, discussed the recommendations from the institution point of view, urging that it would be retrogressive legislation to confuse and confound with lunatics the class of mentally defectives in whose interest the so-called "Idiot Act" of 1836 had been obtained. Dr. Kerr, Chief Medical Officer (Education), London County Council, criticized the proposals to remove from the purview of the Board of Education and the local education authority all the abnormal children found in schools; he thought it would be both imprudent and impracticable; and Dr. Crowley, Medical Superintendent to the Bradford Education Authority, hoped that it might be arranged for the present special schools to continue their work under the education authorities by way of contract with the new Committees for the Care of Mentally Defectives, as contemplated in Recommendation XLII. Mr. J. J. C. Turner, Secretary and Superintendent of the Eastern Counties Asylum for Imbeciles, trusted that a way would be found to utilize the existing charitable institutions which had been doing good service for so many years. The Chairman briefly summed up, and after the usual votes of thanks the meeting dispersed.

British Medical Journal.

SATURDAY, FEBRUARY 13th, 1909.

THE CENTENARY OF CHARLES DARWIN.

AT the present day the counsel, "Let us praise famous men," is in little danger of being forgotten, for the centenaries of great men's birth and those of their death, sometimes of the publication of a particular work, are made the occasion of commemorative oratory and celebrations of one kind or another. There is an inborn tendency in the human mind to ceremonial cult. Formerly each of the saints had his proper festival; in our modern calendar their places have been taken by the warrior, the statesman, the poet, the author, the inventor, the explorer, and the man of science.

This week it is the turn of Charles Darwin, who was born on February 12th, 1809. Darwin is of special interest to medical men, not only because he built a monument of scientific research more lasting than brass, but because he came of a medical stock and was himself intended for the medical profession. His father was a physician at Shrewsbury who was admitted by professional rivals to have the gift of prognosis to which Hippocrates rightly attached such importance. He was a man of great sagacity, strongly opposed to bleeding in the days when surgeries on certain days were like shambles, and who long before typhoid fever was recognized as a distinct disease told his famous son that two utterly distinct kinds of illness were confounded under the name of "typhus fever." He was vehement against drinking, and himself never drank a drop of alcoholic fluid. He had also much of that worldly wisdom without which scientific knowledge does not generally lead to success in medical practice. Charles Darwin's grandfather, Erasmus Darwin, author of *Zoonomia*, was also a physician, and was widely known in his own day as a poet and a botanist, characters which he attempted to combine in his *Loves of the Plants*, ridiculed by Canning in the *Loves of the Triangles*. Charles's brother, Erasmus, one of the few people of whom Carlyle speaks well, took a medical degree, but never practised.

Charles, like his brother, was educated at Shrewsbury under Dr. Butler. The training given there at that time being strictly classical, the school was, he says, to him simply a blank. So little promise of future greatness did he show at this time that his father once said to him, "You care for nothing but shooting, dogs, and rat catching, and you will be a disgrace to yourself and all your family." Even then, however, he was fond of science and literature. He used to sit for hours reading the historical plays of Shakespeare; he read also Thomson's *Seasons*, and Byron and Scott. In after-life, to his own regret, he wholly lost all pleasure from poetry of any kind, including Shakespeare. The imaginative faculty had become atrophied from his overwhelming interest in facts. He worked with his brother at chemistry out of school hours, and was nicknamed "Gas" in consequence. He was once publicly rebuked by the head master for wasting his time in such useless subjects;

to quote his own words: "He (Dr. Butler) called me, very unjustly, a poccourante, and as I did not understand what it meant, it seemed to me a fearful reproach."

As he was doing no good at school his father sent him in 1825 to Edinburgh University, where he stayed with his brother two years. He was sent there to study medicine. He says with much frankness: "But soon after this period I became convinced from various small circumstances that my father would leave me property enough to subsist on with some comfort, though I never imagined I should be so rich a man as I am; but my belief was sufficient to check any strenuous effort to learn medicine." He says the instruction at Edinburgh in those days was altogether by lectures, and these were intolerably dull, with the exception of those on chemistry by Hope. Darwin makes the interesting incidental remark that to his mind there are no advantages and many disadvantages in lectures as compared with reading. Dr. Duncan's lectures on *materia medica* he describes as "something fearful to remember," but the fact that they were delivered at 8 o'clock on winter mornings may have had something to do with this unpleasant recollection. The lectures on anatomy, too, he found not only dull, but disgusting. In regard to this he says, "It has proved one of the greatest evils in my life that I was not urged to practise dissection, for I should soon have got over my disgust; and the practice would have been invaluable for all my future work." Darwin also attended regularly the clinical wards in the hospital. Some of the cases distressed him a good deal, and vivid pictures of some of them remained in his mind. But the hospital work did not interest him much, though he had previously felt a keen interest in clinical work among poor people at Shrewsbury. He attended on two occasions the operating theatre at Edinburgh and saw two very bad operations, one on a child, but he rushed away before they were completed. He never attended again, and he says that hardly any inducement would have been strong enough to make him do so. This, he adds, was long before "the blessed days of chloroform."

Clearly he had no vocation for medicine; on the other hand, he was interested in natural history, and made friends among men who cultivated that branch of knowledge. He was well acquainted with Grant, afterwards Professor at University College, London. One day, when they were walking together, Grant burst forth in high admiration of Lamarck and his views on evolution. Darwin listened in silent astonishment, but Grant's eloquence produced no effect on his mind. He had previously read his grandfather's *Zoonomia*, in which similar views are maintained, but they had no effect on him. Nevertheless, he says, it is probable that the hearing of such views rather early in life maintained and praised favoured his upholding them under a different form in his *Origin of Species*. He was a member of the Royal Medical Society, but, as he bluntly puts it, "much rubbish was talked there."

The idea of his becoming a doctor was given up, and he was sent to Cambridge with the intention of entering the Church. The intention, he says, was never formally given up, but died a natural death when on leaving Cambridge he joined the *Beagle* as naturalist. At Cambridge he says his time was wasted. He got a pass degree without difficulty. He continued to collect minerals with much zeal, but, as he says, quite unscientifically, and he was interested in insects, and in

the habits of birds. From Henslow he acquired a taste for botany, and he must have had some reputation for scientific knowledge among his contemporaries, for one of them who saw him at work with his beetles predicted that he would one day be a Fellow of the Royal Society, a notion which he says seemed to him preposterous. His friendship with Henslow was the turning-point of Darwin's career, for it was on his recommendation that he accepted Captain Fitzroy's offer to go as volunteer naturalist on the famous cruise of the *Beagle*.

Here we must leave him, for the vast work he did in science, though it had indirectly a great influence on the development of medicine, was done in the wide field of general biology. It can scarcely be claimed that his study of medicine did much for his intellectual development in that direction. His aptitude for science was doubtless largely inherited. One cannot avoid the reflection, which has a far wider application than to this particular case, that Charles Darwin could not have accomplished what he did had it been necessary for him to work for his daily bread.

FRIENDLY SOCIETIES AND THE MEDICAL PROFESSION.

THE conference convened by the Charity Organization Society, a full report of which will be found in the SUPPLEMENT, will have served a useful purpose if it induces the leaders of the chief friendly societies to make a serious attempt to meet the objections which the medical profession has advanced to the present system under which these societies provide medical assistance for their members. The conference was attended by, amongst others, representatives of the British Medical Association and of many of its Divisions, and by some of the leading officials of the chief friendly societies.

The moderation of the address with which Dr. James Pearse opened the discussion was recognized by subsequent speakers on the other side. He struck the right note at the beginning by saying that the relations between friendly societies and the medical profession should be cordial, since one of the main objects of friendly societies was the assistance of their members in sickness, while that of the medical profession was the alleviation of sickness. He asserted, as we believe with complete justice, that the medical profession does not object to the principle that friendly societies are entitled to provide for medical attendance on their members in sickness; it objects to the way in which the principle is acted upon, alleging that it is neither fair nor reasonable. Basing himself on a recent actuarial report made for the Manchester Unity of Oddfellows, he showed that the remuneration actually paid by that friendly society for medical attendance to members while actually drawing sick pay worked out at 2s. per sick week, and this calculation does not include the large number of members who consult a medical man for minor ailments without going on the sick-list. The main conclusions of his paper were that the fee paid bore no relation to the work done; that the system was intended to apply only to men in the receipt of ordinary workmen's wages, and not to well-to-do persons and employers of labour; and that

women and children were to be included in medical benefits, the payments made by them, or on their behalf, must be adjusted so as to afford remuneration bearing a reasonable proportion to the medical services rendered.

The speakers representing the friendly societies protested that the statement that members of those societies who were so fortunate as to attain to affluence still took advantage of the medical benefits gave a false impression. While admitting that such cases might occur, they asserted that they were altogether exceptional; but it was once more asserted with some vehemence that the friendly societies would not even consider any suggestion for fixing a wage-limit. Upon this point there may be, we think, some misapprehension, and to illustrate what is meant we will go back to the very complete report on the economic conditions of contract medical practice issued by the Medico-Political Committee of the British Medical Association in 1905. That report contained a mass of information upon contract practice in all its forms, but if attention be confined to the chief friendly societies, which compose the most widely-distributed, and perhaps the most numerous, group of organizations connected with contract medical practice, it will be found that their objects are primarily the insurance of working men earning weekly wages against sickness, loss of employment, and loss of tools. The insurance against sickness was primarily an insurance against loss of wages during sickness; the provision of medical attendance in addition was a natural development of the principle, but, though very general, it is not universal.

Friendly societies, or at any rate many of the most important, including the Oddfellows and Foresters, consist of affiliated bodies in which the local branches have a large measure of independence, although subject to general rules made by annual conferences of delegates, and controlled in certain respects by a central executive. The terms of appointment and remuneration of medical officers are matters within the discretion of the local branches, though the question of remuneration may be influenced by the general rules of the Order relating to the management fund, since medical officers are in many instances paid out of it. It would appear that the possibility of the exclusion of certain members from medical benefits—a point raised by the suggestion to impose a wage limit—would depend on the general rules of the Order. In the report from which we quote, it was stated that what is commonly called the abuse of clubs is perhaps more prevalent and more difficult to remedy in the friendly societies than in any other kind of organization for giving medical attendance to the working classes, and that the main source of this difficulty was that the provision of medical attendance is not their primary object. At previous discussions with representatives of friendly societies two objections to the institution of a wage limit have always been made, and they were repeated at the meeting last Saturday. These are, first, that the friendly societies will not permit the medical profession to dictate who shall and who shall not be admitted to ordinary membership; and, secondly, that a friendly society cannot constitutionally exclude any member from any benefit which the society offers. With regard to the former of these objections, the only reply that need be made is that no such claim has ever been made on behalf of the medical profession; but the medical profession is equally determined to resist dictation and to retain its independence, and it is clearly to the interest of the community, including the members of friendly societies that it should. With regard to the second point, the Medico-Political Committee ascertained in the

course of its inquiry that in many districts the friendly societies do not provide medical attendance, the contribution for medical attendance being optional. Moreover, those friendly societies governed by a central committee, of which the Hearts of Oak may be taken as the type, do not provide medical attendance. It would therefore seem, as the Committee pointed out, that an extension of the distinction between medical and other benefits already to some extent recognized by the friendly societies, would open a way to the solution of the wage-limit problem.

We are glad to believe that one result of the conference is to afford a prospect that the National Conference of Friendly Societies will be disposed to resume the consideration of the subject and to suggest a discussion. Good may be expected to result if the representatives of the friendly societies recognize that the medical officers of these societies have legitimate cause of complaint, and that it is to the interest of the societies themselves to remove them. Sir Thomas Barlow said that if the friendly societies looked only to driving the hardest pecuniary bargain they could with their medical officers, they would not get the kind of service to which their members were entitled. This is true, and Dr. Pearse is not the only medical man who has given up club practice, not without reluctance, because he felt that the conditions were onerous and unsatisfactory. It may be gathered from several of the speeches made at the conference last week that the leaders of the friendly societies are now willing to admit that reform is desirable. On the other side, we can confidently assert that there is no desire to hamper friendly societies in encouraging their members to make provision for sickness, but that medical men to-day will be found no less willing than their predecessors in the past to do all that is in their power, on a basis just and equitable to both parties, to further so desirable an object.

PROFESSIONAL TITLES.

ALTHOUGH the Poisons and Pharmacy Act, 1908, passed during the last session of Parliament, does not directly affect the medical profession, it nevertheless has some bearing upon a point very vital to its interests—namely, the use of titles implying professional qualifications. The Act is of the nature of a compromise between the views of those on the one side who hold, and as we think rightly hold, that inasmuch as a corporate body cannot go through a curriculum, pass examinations and receive a qualification, it should not be allowed to use the titles conferred upon persons who have done so; and the views of those on the other side who hold that companies carrying on the business of chemists should be allowed to use certain titles without restraint.

Whilst the representative bodies of the chemists were anxious to restrict the use of their descriptive titles to those who really possessed them, there already stood upon the Statute Book a proviso which, to a certain extent, weakened their position; this, commonly known as the "widows' clause," was intended to preserve to the widow of a deceased chemist the fullest interest in her husband's business by enabling her or an executor or trustee to carry it on. Although it was necessary that a qualified assistant should be employed, yet the responsible proprietor might be

unqualified, and the qualified assistant personally not known to the general public by name. This privilege accorded to the widow, executor or trustee, a majority of the chemists were unwilling to give up, and the principle of possible lay proprietorship once admitted, it became more difficult to withstand the claim of the companies to assume the style of pharmaceutical chemists or what not. What has been gained in the new Act—and it is a substantial gain—is that companies trading as chemists must employ a superintendent who is duly qualified and registered, and who is not similarly employed by any other company or firm, and further that on any premises where this superintendent does not personally conduct the business there must be a duly registered chemist whose name and certificate of qualification must be conspicuously exhibited on such premises. These requirements are absolute, but, if they be observed, it is competent for a company to use the description of chemists and druggists, or of dispensing chemists and druggists, provided that the superintendent before alluded to is a member of the board of directors, or of the firm or partnership. It is true that the title of pharmaceutical chemist is not conceded to a company, but the public will hardly draw the fine distinction between "dispensing chemist and druggist" and "pharmaceutical chemist." Broadly speaking, then, while the operations of companies and partnerships are brought under regulation, the use of some titles which hitherto implied personal qualification has been conceded to bodies corporate in which there need be but one qualified person.

Medical and dental companies constituted on similar lines, namely, with one qualified person on the list, have from time to time been brought to notice, and care must be taken lest this new departure with regard to chemists be not taken as affording a precedent for any similar weakening of the meaning of the professional titles of medical men or dentists. We have no "widows' clause" to hamper our position in this matter, and so long as the only effective restraint on unqualified practice lies solely in the direction of a prohibition of the assumption of medical or dental titles by the unqualified, the full meaning of those titles must be preserved in all its integrity.

The whole issue is another example of the inefficiency of medical legislation in this country, which deals with words and not deeds, and necessitates jealously safeguarding titles and descriptions with a care which to the outside public may appear exaggerated.

THE EMMANUEL MOVEMENT.

IN the JOURNAL of February 6th, page 360, it was stated that every neurologist of standing in Boston had condemned the Emmanuel movement, but that, nevertheless, the clerical healers had continued their ministrations, dispensing with medical direction. Events move so fast that it is not easy to keep up with them. From a letter published in the *Boston Medical and Surgical Journal* of January 21st, which came into our hands almost immediately after our last issue had gone to press, it appears that a medical advisory board had in the meantime been formed. The members of this board are Drs. Joel E. Goldthwait, James G. Mumford, Richard C. Cabot, and Joseph H. Pratt. These gentlemen state that they believe the Emmanuel movement to be sound in its fundamental principle, which

is that the effective co-operation of physician and minister is of value to many sick persons. Assuming that the sick person has faith in religion—the precise theological shade is immaterial—that statement is so trite as to be a truism. The members of the medical advisory board go on to admit that mistakes have been made, and that “methods which seemed “adequate at an early stage of the work now need to “be improved, and in particular a closer relation “between the physician and the clergyman is “desirable.” In order to preserve and extend the co-operation between the two, the following rules have, they say, recently been adopted by the Emmanuel clergy: “(1) No person shall be received for treatment unless with the approval of, and having been “thoroughly examined by, his family physician, whose “report of the examination shall be filed with the “minister’s records. (2) No patient shall be referred “for diagnosis or treatment to any specialist or “assistant save with the advice and consent of the “patient’s own physician. (3) All patients who are “not under the care of a physician must choose one, “and put themselves in his care before they can “receive instruction at Emmanuel Church. To “those who ask for advice in this choice there “shall be handed a printed alphabetical list of “all the general practitioners (internists) attached to “the visiting and out-patient staffs of the Boston City “Hospital, the Carney Hospital, the Homeopathic and “the Massachusetts General Hospital.” From this, or from any other source which the patient may prefer, a physician is to be selected. It rests wholly with the physicians, and not with the Emmanuel clergy, to decide whether a patient shall be referred to a neurologist or other specialist, and which cases, if any, are suitable for treatment by moral and religious education at Emmanuel. “The advisory board,” it is stated, “is concerned solely with advice and counsel “regarding the manner of conducting the work, and “in no sense with the examination, control or treatment of individual patients.” The well-meaning physicians who formed the advisory medical board, however, appear very quickly to have been awakened to the fact that their position was open to misunderstanding, for in the following issue of our Boston contemporary (January 29th) we find them explaining that they do not approve of the Rev. Dr. Worcester’s treating any one who is not actually and constantly the patient of some physician. They state that “the “physician must be in control throughout.” They add that they do not think this full medical control has been obtained heretofore, and that “in this “respect” they disapprove of much that has been done at Emmanuel and wish to change it. They have thought it expedient to substitute the following for the third of the rules above printed: “No “person shall be accepted for advice by the clergy “except on the recommendation of and in co-operation with a responsible physician. In case the “clergyman’s opinion is asked regarding the choice “of a physician, the inquirer shall be referred to “the annual reports of the principal hospitals “of this city. The physicians whose names “appear in these reports will, of course, not be “regarded as responsible for or in any way connected with Emmanuel, whether they may have “said ‘Yes’ or ‘No’ in answer to the question which “we asked them in our personal letter regarding fees.” They conclude by saying that the Rev. Dr. Worcester realizes the wisdom of discontinuing any semblance of a clinic. “To emphasize this he has discontinued “all medical examinations at the church and abolished “the former medical staff. He does not intend to “treat disease. He simply stands ready to assist in

“the moral and spiritual re-education of any person “whom a physician asks him to see.” These, as Mr. Peter Teazle would say, are noble sentiments. But we confess we are somewhat doubtful how long it may be before the worthy divine is driven by the unreasoning faith of patients, and perhaps a little by his own belief in his healing mission, to go back to the ways he has, evidently in deference to a strongly-pronounced professional opinion, been induced to abandon. In saying this we do not wish to be understood as hinting a doubt as to his perfect good faith. But the gift, real or supposed, of healing the spirit is sometimes dangerous to the possessor, and experience has shown that it very easily leads him to look upon the soul’s tenement of clay as being an appanage of his spiritual kingdom.

DIFFICULTIES UNDER THE MIDWIVES ACT.

THE measures hitherto adopted to secure smooth and satisfactory working for the Midwives Act, 1902, cannot be said to have been successful. The rules and regulations of the Central Midwives Board (appointed under the Act) require for their effective operation the support of registered medical practitioners; no serious attempt was made in the first place to ensure such support. The midwife is compelled to advise that the assistance of a medical practitioner must be obtained in all cases of difficulty and urgency. A midwife who disregards this rule is liable to have her name removed from the roll of midwives. Such a regulation takes away the discretionary power of the patient or of those immediately concerned, and leaves no alternative, without serious possible consequences, but the acceptance of the midwife’s advice. The real responsibility of the registered midwife ceases when she has taken steps to give effect to the rule requiring her to seek medical assistance. It does not appear to have been thought necessary by the State to make provision for the final and essential step in this stringent regulation. Difficulties were soon encountered in consequence of this omission. Midwives found it was not always easy or possible to obtain medical help under these circumstances. After considering numerous complaints arising in this manner, the authorities concerned appealed to the Local Government Board to help in the solution of the difficulty. A circular was then addressed by the Board in February, 1908, to local authorities asking them to draw up regulations calculated to secure for the people the advantages sought by the Act in a manner satisfactory to the members of the medical profession. In response to this appeal some boards of guardians have issued regulations and accepted some measure of responsibility. This step does not appear to have removed the difficulty; indeed, in some instances it has accentuated the point of grievance. In a case at Halifax recently reported in the local press the method has failed. The guardians sent out a circular to medical men and the midwives, and placed in the hands of midwives forms for securing medical attendance which, to the lay mind, have all the appearance of orders. The guardians expressed their willingness to pay in the case of poor persons, but declined to pay the doctor in cases in which they think the patient is able to pay, leaving the doctor to struggle for his remuneration. The Halifax Division of the British Medical Association, after carefully considering the circular issued by the board of guardians, resolved to advise members not to act under the local regulations after a certain date unless the guardians were willing to modify their circular in regard to the clause

dealing with the remuneration of medical men summoned in urgent cases on the messages from midwives. This resolution was forwarded to the guardians, who agreed to receive a deputation from the Division on the subject. Nothing came of it. The guardians appeared to think they have exerted their powers to the full extent, or, at any rate, appeared unwilling to go further, declining to give a guarantee that the practitioner called to the assistance of a midwife should be remunerated by the local authority except in the case of poor persons. This, in the view of the Halifax Division, did not carry the matter beyond the scope of the powers of the guardians under the existing Poor-law Acts. A large and representative meeting of the Division held recently, unanimously resolved to reaffirm the previous resolution, to the effect that all members of the Division be advised not to act under the regulations of the guardians as they at present exist after March 31st, 1909. Neither the guardians nor the local Division can be said to be wholly to blame for this unsatisfactory result. It should not be left to local authorities, liable to be influenced by considerations wholly or in part irrelevant to the issue, to decide and regulate essential principles affecting the administration of important Acts. It is undesirable that matters of this kind should be the subject of local discussion often attended by misunderstandings and friction which ought not to exist between medical men and public bodies. The subject is one of the points referred to the Departmental Committee at present engaged in considering the working of the Midwives Act, and as a result of its deliberations and recommendations the present difficulties may be overcome by the establishment of some satisfactory scheme applicable uniformly throughout the country. The fact that a Departmental Committee has been found necessary, with this matter as one of its principal terms of reference, should diminish the annoyance felt in places where difficulties have arisen. The effect of the combined action of the profession in Halifax is an assertion of the principle that the medical man is a free agent, at liberty to attend on call of a midwife if he is able and willing to do so, as before the issue of the local regulations, and in cases where there is reasonable uncertainty as to the remuneration to refer such cases to the relieving officers.

UNQUALIFIED PRACTICE AND SECRET REMEDIES IN GERMANY.

THE German Government has introduced a bill to regulate the practice of healing by unqualified persons and to limit the trade in secret remedies. While not absolutely prohibiting unqualified practice, the bill proposes to penalize the treatment of either men or animals at a distance—that is, without examination—and also the treatment of human beings for gonorrhoea, chancre, or syphilis; the use of any general anaesthetic remedy; and treatment by hypnosis or by mystical processes (*mystischen Verfahrens*). While the bill does not actually forbid the treatment of infectious or notifiable diseases, this may be prohibited under certain circumstances by police ordinance. Every unqualified person practising the art of healing as a trade will be required to notify himself to the police, giving particulars of his education and character. He will have to keep trade books, and must not treat patients at a distance, and under certain circumstances he may be forbidden to practise. The Imperial Board of Health will have discretionary power to limit the trade in certain means or materials for preventing, mitigating, or curing diseases or injuries of men or animals. The bill proposes to

forbid the publication of misleading advertisements relating to the treatment of disease, of advertisements offering to treat disease by letter, or advertisements of remedies for sexual disorders, for the relief of sexual weakness, or the prevention or removal of pregnancy, and of all secret remedies. Professor Rumpf of Bonn has suggested¹ certain amendments which he regards as necessary. He urges the inclusion of all infectious and notifiable diseases in the prohibited list, as it is in the interest of the public health that these should be recognized and brought to the notice of the authorities without delay. Further, he would include unqualified practitioners in midwifery among those to be brought under the scope of the law. He would make it incumbent upon all unqualified persons having places of business in more than one police area to notify in each, and he would make it penal for such unqualified persons to advertise or publicly announce their tolerance by the police by the word "licensed" (*Koncessioniert*). He thinks their books should be open to the inspection of the medical officer of health for the district, and should contain the name of each patient, his complaint, the diagnosis, and prescription. He wishes the words "its consequences" to be added after syphilis, and he desires to include words which will prohibit the advertising or puffing of quacks who may live outside the jurisdiction of the German courts. He would further penalize the advertisements of any means or remedies "for curing or removing obstructions" (*Störungen*). The bill proposes to forbid the advertisement of any secret remedies except in trade journals, such journals to be scheduled by the Commissioners of the Imperial Council, and to this Professor Rumpf would add words prohibiting "causing of the public by agents." The penalties contemplated by the bill for a breach of this law are six months' imprisonment and a fine of 1,500 marks (£75), or either. We trust the German Government will succeed in passing this bill. Even without Professor Rumpf's amendments it promises to be an effective means of preventing the trade in secret medicines, and will do much to restrict the operations of the rogues who thrive on the weakness and fears of those who put themselves in their power by consulting them. The need for such legislation is not less obvious in Great Britain, and public opinion here cannot fail to be influenced by the fact that Germany, after the experience of forty-five years of free trade in medicine, has recognized that such a state of things is injurious to the commonweal and needs legislative regulation.

THE SCHÄFER METHOD FOR RESTORING ANIMATION IN THE APPARENTLY DROWNED.

SOME months ago the Chief Surgeon of the Metropolitan Police applied to the Royal Society of Medicine for an expression of opinion as to the best method for restoring animation in the apparently drowned, and a committee appointed to prepare a report decided in favour of the "Schäfer" method.² They recommended its adoption to the exclusion of all other methods, because it is simple, available under a variety of circumstances, and can be carried out by a single person, while the directions are "incapable of being misunderstood."³ As a consequence of this report a broadside of Instructions has now been issued by the police; it contains

¹ *Soziale Medizin und Hygiene*, 1909, p. 20.

² *BRITISH MEDICAL JOURNAL*, 1905, vol. ii, p. 1405; *Med. Chir. Trans.*, 1904, vol. lxxvii, p. 602.

³ *Proc. Roy. Soc. Med.*, vol. ii, No. I, p. 5.

reproductions of four good photographs illustrating the two movements, and it may fairly be said that it would be difficult for anybody to misunderstand the directions. "With the arms extended" is perhaps not quite clear; "stretched out in front of the head" would have been a better phrase for the uninitiated, but then there are the figures to help. It is to be noted that Professor Schäfer's recommendation to "place a thick folded garment beneath the chest and epigastrium" has been omitted, probably in the interests of simplicity and to avoid a second of wasted time, but it is almost a pity, especially as the operator, if he knows what awaits him in the way of physical work, will certainly throw off his coat before beginning. "When natural respiration has commenced, the patient should be allowed to lie in a natural position on one side," say the instructions. It would surely not have involved any sacrifice of lucidity to embody the recommendation of the committee to place the patient on the *right* side. The liver is extremely congested, and the heart recovering from over-distension, and the left lung rids itself more readily than the right of water and mucus. Other points that render the method preferable to that of Sylvester are the prone position, which allows water and mucus to run out of the mouth, and keeps the tongue forward; upward pressure of the diaphragm exerts a stimulating action on the heart; "expiration" or compression is a better stimulus to the respiratory centre than expansion; and finally, though this is doubtful, more air can be exchanged per minute. Any one who has had to perform artificial respiration on a big, heavy, or muscular man for more than a very few minutes knows that the effort becomes very exhausting, and that the efficiency of the Sylvester expansion movements rapidly diminishes so soon as the operator is tired. Where only one person is available there is no doubt that a method which takes mechanical advantage of body weight rather than muscular effort has an advantage outweighing minor theoretical superiorities; and if, as appears probable, theoretical precision is combined with the greater simplicity of the new method, it is to the advantage of the public for the police, following the lead of the Royal Life-saving Society, to adopt it.

VIVISECTION AND THE POOR.

The antivivisectionists have had the flash light of truth turned on them of late so steadily that it is no wonder they have shown signs of discomfort under the exposure. Their wailings in the newspapers are not worth serious notice, but are amusing as they are so obviously the appeals of rival showmen. Their object is so plain and their controversial methods are worn so thin by constant use that all but a few fanatics must agree with Mr. Stephen Paget when he said, at the inaugural meeting of the Dublin Branch of the Research Defence Society, that sensible people are sick unto death of them and their stale stock of calumnies which they persist in offering to an indifferent public. Not even theological controversies which have grown musty and out of date are so wearisome as antivivisectionist literature. One may read feet or yards of the effusions of Mr. Stephen Coleridge, Miss Beatrice Kidd, Dr. Hadwen and the other scribes who have adopted as a profession the systematic vilification of men who give their lives to the enlargement of the boundaries of knowledge for the good of their kind, without finding a new point, a new fallacy, or even a new lie. One should therefore perhaps be thankful to the Secretary of the London and Provincial Antivivisection Society for

putting forward something which strikes us as novel. As it is particularly silly, it was natural that it should come from the dullest of the many wearisome writers on the "torture" of animals in laboratories. In that illuminating medium, *Reynolds's Weekly Newspaper* (January 31st), we find Mr. Sidney Trist writing as follows: "The vivisectors allege that experiments on animals are useful but not conclusive until tested on man. Who is the final test tube? The vivisector, or those well-to-do persons who are likely to be profitable patients? By no means. The absolute test in all these matters is money. The man who is likely to physically benefit, if it is possible, from vivisection, is the wealthy man or woman; the man who is likely to be the final test tube—to make sure that the experiment is a success—is the man who has least to give and only his life to lose." In a letter about the Dublin meeting above referred to, Mr. Trist says that one of the speakers "talks nonsense." We thank the courteous Secretary of the London and Provincial Antivivisection Society for teaching us these words, which we make no scruple in applying to himself. The opposition to the dissection of the human body lasted much longer and had an infinitely stronger support than the campaign against vivisection. It was not until 1832 that the Anatomy Act was passed. In the debate on the subject the argument that the measure was for the benefit of the rich was used by some one of the same temper of mind as Mr. Sidney Trist. He was answered by Macaulay in a passage which we quote, because it applies exactly to Mr. Trist's fustian about "the wealthy man or woman" and the "man who has least to give and only his life to lose." On February 27th, 1832, Macaulay said in the House of Commons: "Again as to bad surgery: this is of all evils the evil by which the rich suffer least and the poor most. If we could do all that in the opinion of the Member for Preston [we do not know who he was, but he would seem to have been an archetype of Mr. Trist] ought to be done, if we could prevent disinterment, if we could prevent dissection, if we could force every student of medical science to go to the expense of a foreign education, on whom would the consequences fall? On the rich? Not at all. As long as there is in France, in Italy, in Germany, a single surgeon of eminent skill who is, to use the phrase of the Member for Preston, addicted to dissection, that surgeon will be in attendance whenever an English nobleman is to be cut for stone. The higher orders in England will always be able to procure the best medical assistance. Who suffers by the bad state of the Russian school of surgery? The Emperor Nicholas? By no means. The whole evil falls on the peasantry. If the fees of surgeons should consequently rise, if the supply of regular surgeons should diminish, the sufferers would be not the rich, but the poor in our country villages, who would again be left to mountebanks and barbers, old women and charms, and quack medicines. The honourable gentleman talks of sacrificing the interests of humanity to the interests of science, as if this were a question about the squaring of the circle or the transit of Venus. This is not a mere question of science; it is not the unprofitable exercise of an ingenious mind; it is a question between health and sickness, between ease and torment, between life and death. Does the honourable gentleman know from what cruel sufferings the improvement of surgical science has rescued our species? I will tell him one story, the first that comes into my head. He may have heard of Leopold, Duke of

"Austria, the same who imprisoned our Richard
 "Coeur-de-Lion, Leopold's horse fell under him
 "and crushed his leg. The surgeons said that
 "the limb must be amputated, but none of them
 "knew how to amputate it. Leopold, in his agony,
 "laid a hatchet on his thigh, and ordered his servant
 "to strike with a mallet. The leg was cut off, and the
 "Duke died of the gush of blood. Such was the end
 "of that powerful Prince. Why, there is not now a
 "bricklayer who falls from a ladder in England who
 "cannot obtain surgical assistance infinitely superior
 "to that which the Sovereign of Austria could com-
 "mand in the twelfth century." The moral of the
 "tale may be further pointed for the instruction of
 "Mr. Trist and his friends by reference to the fact that
 "since 1832 surgery has made greater advances than it
 "had made during all the centuries of recorded time
 "before the date of Macaulay's speech. And it is a fact,
 "which no candid person who knows the history of its
 "progress can deny, that the advance has been
 "mainly due to the application of knowledge acquired
 "by vivisection. It may be added that this advance
 "has benefited the poor far more than the rich.

SCHOOLBOYS AND LONG RACES.

IN another column we publish a letter signed by Sir
 Lauder Brunton, Sir Thomas Barlow, Drs. Goodhart
 and Hale White, and Sir Alfred Fripp, in which the
 statement is made "that school and cross-country
 "races exceeding one mile in distance are wholly
 "unsuitable for boys under the age of 19, as the con-
 "tinued strain involved is apt to cause permanent
 "injury to the heart and other organs." This opinion
 is expressed in a letter to Mr. Herbert Farmer, an
 old Harrovian and Middlesex county football captain,
 who himself considers such races highly injurious;
 but we feel inclined to ask whether, if there
 were definite evidence of "permanent injury" to
 and "wreckage" of boys' lives, we should not have
 had an expression of opinion from the medical officers
 of public schools which would have prevented the
 continuance of the practice. A race or wrestle for
 sport is like a race or struggle for life. The body is
 spent to the utmost, the consumption of oxygen
 temporarily becomes greater than the supply, and
 lactic acid and other products of incomplete oxidation
 poison the heart and muscles. But the body has been
 evolved and is built to stand such strains in the
 struggle for existence; it recovers, as a rule, quickly
 from its temporary intoxication by fatigue products.
 The healthy boy is far less likely to push himself to
 the extreme of exhaustion than the man. The schoolboy,
 as a rule, is in better training than the city week-end
 athlete (over 19), who is handicapped by long hours of
 office work and indulgence in tobacco; there is a great
 deal of talk about the athlete's heart, but very little
 definite proof that permanent cardiac trouble is pro-
 duced by over-indulgence in athletics *per se*. In the
 type of athletes who suffer from heart trouble,
 syphilis and indulgence in alcohol and tobacco
 have to be reckoned with. Disorders of cardiac
 action produced by excessive effort in the un-
 trained state quiet down and entirely disappear
 with rest and abstention from tobacco, and leave,
 we believe, the heart not one whit the worse.
 From pathologists we can gain no definite evidence
 that the hearts of athletes are enlarged beyond that
 degree which is the natural response to the increased
 work required of it. The navy and the blacksmith
 carry out daily for many years the severest toil, while
 the athlete's period of strain is usually short. We
 have no evidence that such toil, apart from syphilis
 and alcohol, causes vascular degeneration. We fail to

see any reason for stopping boys running cross-country
 races so long as they are fit and enjoy it, and the
 distances are of moderate length. The practice
 which requires severe criticism is that of com-
 pelling all boys alike to run these races. If the boys
 are left to themselves only those constitutionally
 fit for such exercises will take to it. The others
 will stand aside. If compulsory games and runs
 are enforced, there ought to be strict medical
 inspection, so that none of the unfit and untrained
 may be compelled to do muscular work beyond their
 powers. The training and development of the boys'
 physique should be as important a part of the school-
 master's charge as the training of mind and character.
 In this respect reform is urgently wanted, but we
 cannot see any reason for frightening all boys off
 cross-country runs, and setting up the idea that it is
 safe to indulge in such runs after 19, and not before.
 Boys should be taught to run, not to win or break
 records, but to improve their physique and increase
 their enjoyment of life. A return to the true spirit of
 sport is what is required.

THE WAR AGAINST THE MOSQUITO.

SIR PATRICK MANSON has been entertained at dinner
 by the Authors' Club, Mr. Percy White being in the
 chair. In his speech he said that in his early years of
 tropical experience he was in the island of Formosa,
 and one disease had a special fascination for him—
 elephantiasis. Later he went to Amoy, a large town
 on the coast of China, where he saw many more cases
 and many more forms of the disease. Still he failed
 to find an explanation. In 1874 he came to London,
 where he heard that Timothy Lewis had discovered
 that in the blood of a proportion of the inhabitants in
 certain districts of India there was to be found an
 organism, which he called the *Filaria sanguinis*
hominis. These parasites Lewis had found in more
 than one instance in association with elephantiasis,
 or elephantoid diseases. On his return to China
 in 1876, Sir Patrick Manson discovered that the
 parasites were present in some districts in 10
 per cent. of the population; in other districts
 they were present in 50 per cent.; while in
 other places they were not found at all. He
 described how he ultimately succeeded in tracing
 the filaria into the mosquito. It was now absolutely
 sure that certain kinds of mosquitos were the means
 for the transmission of the filaria of the blood, and
 therefore of those diseases to which that parasite gave
 rise. In the early Nineties he interested himself in
 the malaria parasite, discovered some time before by
 Laveran in Algiers. He felt convinced for many
 reasons, epidemiological as well as biological, that the
 insect was the intermediary of the malaria parasite.
 Being in England, he was unable, for want of material,
 to test and work upon this hypothesis. He sent a
 paper on the subject to the BRITISH MEDICAL JOURNAL,
 and the Editor said the idea seemed a good one, and
 asked why he did not go to work upon it himself.
 But to do that he would have been obliged to go to
 a malaria country. A sum of money was promised by
 the British Medical Association for this purpose,
 on condition that the Royal Society would give a
 similar amount; this, however, the society could not
 see its way to do. About that time he met Professor
 Ronald Ross, who took up the idea and worked it
 out to the brilliant conclusion which all the world
 knew. The doctrine was received by many with
 ridicule. But there was one man in England at that
 time who recognized the importance of the discovery.
 That was Mr. Joseph Chamberlain, then Secretary of
 State for the Colonies, who, when asked for a

sum of money for certain experiments, at once acceded to the request. The experiment in the Roman Campagna, with the complementary experiment in Italy, and the work of Professor Ross and many other scientific men, had absolutely confirmed the mosquito-malaria theory, and now, in most places where malarial fever was rife, the practical application of the theory was leading to important advances in sanitation. The discovery of the relation between mosquitos and yellow fever had rid Havana of that disease, and that discovery was enabling the Americans to construct the Panama Canal. There was proof that the tsetse fly acted in a like manner as regards the fly diseases of cattle and the fly disease—the sleeping sickness of man. They knew that a certain kind of tick was the medium by which relapsing fever was conveyed. They were fairly sure that other diseases were conveyed by bugs and lice. Doubtless the result would be practical measures which would tend to minimize the dangers of these diseases, if not to prevent them altogether. Several tropical diseases, notably malaria and yellow fever, were still geographically limited; but if precautions were not taken in time, he believed that, with the opening up of the Panama Canal and by the repeated passage of rapid steamers across the Pacific, yellow fever would be introduced into the Sandwich Islands, Manila, and to the Continent of Asia. Further, if measures were not taken to prevent the introduction of fever-carrying mosquitos into some countries hitherto free from malaria, by-and-by these countries would become exceedingly unhealthy and malarious. The moral was that discovery was of little use unless it had practical application. Damp was not the cause of disease. It was damp in the form of puddle and swamp that was so admirably suited to the mosquito. Again, it was not dirt that caused disease, but the ticks and other carriers of germs which thrive in dirt. He concluded with a note of warning as to the preventable calamity which he considered was hanging over Asia and the Pacific by the probable spread of yellow fever to the former and malaria to the latter through the introduction of disease-carrying insects.

LEPROSY IN NEW SOUTH WALES.

THE report for the year 1907 regarding leprosy in New South Wales has just been received. The details of the new cases have been carefully worked out with Dr. Ashburton Thompson's usual thoroughness, with the co-operation of Dr. D. Wallace, of the Coast Hospital and Lazarets. During 1907 seven persons were reported as suspected lepers, but after careful investigation only five of these were certified, of whom four were ultimately admitted. The fifth case, a Greek sailor, was, in accordance with the Immigration Restriction Act, detained on board his vessel until its departure. The other four cases were respectively a native of Lahore, who absconded, and could not be traced by the police; a woman born in Australia in 1856, her mother being a native of London and her father the son of Dutch parents it is said, but a native of Penang (the patient visited Singapore in 1877 and lived for some time in Batavia); and two Chinamen. The report gives elaborate details of the examination (surveys they are called) of the cases admitted previously to the year 1907. The value of these reports lies in the fact that they apply to a limited field and to a limited number of patients. It is really a great mistake to suppose that for the clinical study of leprosy a large number of cases is necessary. On the contrary, where numerous lepers

are congregated together, investigators, who are only human, lose some of their enthusiasm, another factor in this depressed attitude being the monotony of life and climatic influences. In leprosy areas, better far to study and follow up a few selected cases. This applies especially to the therapeutic aspect of this baffling complaint. Dr. Ashburton Thompson has been well advised in adding tabular statements as to the incidence of leprosy in the other States of the Commonwealth.

THE ETIOLOGY OF GOÏTRE.

CAPTAIN ROBERT MCCARRISON, M.B., B.Ch., I.M.S., communicated recently to the Royal Society the results of a research to determine, by experiment on man, whether goitre was caused by matter held in suspension in goitre-producing waters, and to ascertain, as far as possible, the nature of the suspended ingredient which had been surmised to be responsible for the production of the disease. The experiment was made at Gilgit, Kashmir, and the results, of course, can only be directly applied to goitre as it occurs there. Thirteen individuals, including Captain McCarrison, were given suspended matter which had been removed by filtration from goitre-producing water every morning before the first meal of the day. Captain McCarrison and three others developed enlargements of the thyroid gland. The experiment was repeated in the case of eight individuals who were given the same suspended matter, which had previously been boiled for ten minutes; in no case did any enlargement of the thyroid gland occur. The conclusion drawn from these results is that goitre is due to a living organism of disease present in the water. The incubation period of experimentally-produced goitre was thirteen to fifteen days. The suggestion is made that the organism of goitre exists as an intestinal parasite in goitrous individuals, since an intestinal antiseptic appeared to have a marked curative effect. Experiments were made on monkeys to test the possibility of the spread of the disease by the faeces of infected individuals but with negative results. Plentiful amoebic infection of the intestine was found in the majority of cases of goitre examined. It is not known, however, whether amoebae have any relationship to the disease.

DR. SIDNEY MARTIN will deliver the second Lettsomian Lecture on functional disorders of the stomach and intestines, their diagnosis from organic disease, and treatment, before the Medical Society of London, on Monday next at 9 p.m.

DR. F. W. MOTT, F.R.S., Fullerian Professor of Physiology and Pathologist to the London County Council, will deliver a course of lectures at the Royal Institution on the evolution of the brain as an organ of mind on six consecutive Tuesdays—February 23rd, March 2nd, 9th, 16th, 23rd, and 30th—at 3 p.m. In a further course of lectures Dr. Mott will deal with the structure of the human brain.

THE Prince and Princess of Wales will honour the Royal College of Surgeons of England with their presence at the delivery of the Hunterian Oration by the President, Mr. Henry Morris, on Monday, February 15th. The Prince of Wales has graciously consented to become an Honorary Fellow of the College, and the Diploma of Honorary Fellowship will be presented to His Royal Highness in the presence of the Council on that day.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

LIVERPOOL.

THE MILK SUPPLY OF HOSPITALS.

SOME time ago the Liverpool Medical Institution appointed a special committee of its members to consider whether the Liverpool voluntary hospitals should be advised to take action to ensure greater purity of their milk supply with special reference to tuberculous infection, and to report thereon to the institution. The following formed the committee: Mr. T. H. Bickerton (President), Sir Robert Boyce (Chairman), Dr. Buchanan and Dr. H. H. Clarke (Secretaries), Dr. Hope, Dr. Annett, Dr. E. E. Glynn, Dr. C. A. Hill, Dr. N. Percy Marsh, and Dr. W. B. Warrington. These names are fairly representative of the voluntary hospitals of the university and of the public health department. The report, which has recently been presented to the institution and adopted, lays emphasis on the importance of a pure milk supply, especially in the case of invalids and children, and draws attention to the fact that more than 5 per cent. of the samples of railway-borne milk were so deficient on chemical analysis that legal proceedings were taken; 5.4 per cent. contained tubercle bacilli, and 72 per cent. contained organisms commonly present in the excreta of cattle. The report states that

Pure milk of good quality can only be obtained from healthy cows, kept clean, under good hygienic conditions, and properly fed. The milk should be rapidly cooled, and delivered as quickly as possible to the consumer, being protected from contamination during transit. Many of the best dairies at the present time are conducted under conditions favourable to the supply of pure milk, and the problem is therefore how best to insure that our voluntary hospitals be supplied only from such dairies.

In Appendix I to the report are given suggested forms of contract for the supply of pure milk, designed to secure the following conditions:

1. Systematic inspection of the farm.
2. Periodical analysis of the milk for fats, solids, and adulteration.
3. Bacteriological examination at intervals for the usual infective organisms, more especially tubercle, and for other bacterial examination.
4. Periodical application of the tuberculin test.
5. The farm and accessories to be properly equipped and kept up to an approved standard of hygienic efficiency.
6. The use of special milk cans—or chums—for transport of convenient size, rain-proof and dust-proof, and capable of being easily sealed. These to be registered, numbered, and stamped on the outside with the tare weight.

In Appendix II the value of the tuberculin test is discussed, and the opinion is expressed that it is not safe to use the milk of any tuberculous cow for human food, and that the tuberculin test is the best means at present available for detecting tuberculosis in cattle. The real objection to its use is said to arise mainly from an uneasy suspicion that tuberculosis is exceedingly prevalent amongst the cattle of Great Britain, and from a still more uncomfortable uncertainty as to the quarter on which the loss will fall if tuberculosis in cattle is to be eliminated.

A conference will shortly take place between representatives of the governors and medical boards of the voluntary hospitals and the Milk Committee with a view to giving effect to the foregoing conclusions.

VACANT POST OF MEDICAL OFFICER TO THE POLICE IN LIVERPOOL.

The Corporation of Liverpool has advertised in the local press for a medical officer to attend the members of the police force of the "B" Division, including the members of the staff departments residing within the division. The advertised salary is fixed at £60, to be increased to £80 per annum after five years' service. The "B" Division comprises about 280 men, and the members of the staff department residing in the district number about 50, so that the salary offered by the wealthy and important Corporation of Liverpool for attendance on its police constables works out at less than 4s. a head per annum. It is stated that in London and other cities the payment

works out at or about 10s. a head. It is true that in Liverpool the Corporation supplies the medicines at its own expense, but, on the other hand, the medical officer has several anxious and responsible duties to perform besides the actual treatment of the sick constables. Thus, a daily report has to be made of those who go off duty through illness, and of those who are able to return to duty, and the Watch Committee may call for a special report on any constable who is off duty. Further the medical officer is required to report on cases applying for superannuation, and has to spend about two hours each month in examining recruits. It is worthy of remark that the retiring medical officer was in receipt of £100 per annum, to which sum the salary was raised from £80. The Corporation seems to think that the resignation of the medical officer is a favourable occasion to effect a paltry economy in dealing with the lives and health of the constables it employs. This is all the more remarkable at the present time when it is announced that the municipal budget for the current year will involve a very substantial increase in the rates. The rates must be borne by all alike, but the idea of the Corporation seems to be that the medical profession is to be made to pay a special contribution by the docking of the salaries of such of its members as are in the service of the Corporation.

MANCHESTER AND DISTRICT.

THE NATIONAL ASSOCIATION OF MIDWIVES.

THE National Association of Midwives at its meeting in Manchester last week discussed the omission from the Departmental Committee now considering the working of the Midwives Act of any direct representative of the midwives of the country. It was stated that it had become almost a custom in appointing such committees to add at least one representative of any interest that might be affected by the inquiry. This was quite fitting, as such representatives having practical experience of the matters to be discussed, might often be able to throw considerable light on the subjects. The association passed a resolution respectfully asking that a direct representative of the midwives might be added to the committee.

THE MANCHESTER HOSPITAL FOR SKIN DISEASES.

The remarkable increase in the number of patients treated at this hospital, largely owing to the "light" treatment, is shown by some figures given at an annual meeting of the subscribers to the hospital. In 1888 the patients treated numbered 632; in 1901 they had increased to 1,989, while last year they numbered 8,796, making 48,916 attendances during the year. The hospital has a most elaborate and complete department for treatment by Finsen light and x rays, which caused patients to be drawn from almost every part of the country. In 1902, out of over 58,000 attendances no less than 28,895 were for the "light" treatment. The contributions received from patients last year amounted to £1,131, of which £731 was from the out-patients. There was a slight decrease from private and "light" patients, and on the full year's working there was a deficiency of £656. An appeal was made for £2,500 to free the new building from debt, and also for £1,000 to place the income account on a good footing. The regular subscriptions needed increasing by something like £650. Dr. Lancashire, referring to the medical report, called attention to the great increase in the number of cases of parasitic skin diseases which the hospital had treated. He thought that if their figures could be taken as any indication of the prevalence in Manchester and Salford of that class of disease, they were worth the consideration of the medical officers of health. The cases were extremely difficult to eradicate because, even if cured by attendance at the hospital, the patients on returning home were soon reinfected, and the only real remedy was to eradicate the disease from the people's homes.

Inquiries on the subject fail to show any greater prevalence of these diseases than usual, nor does Dr. Lancashire say anything except that the hospital has treated more cases. This is undoubtedly due to the fact that health visitors, school inspectors, and teachers are making more rigid and systematic examinations of school children than formerly, and urging parents to obtain treatment. The Children's Act passed in the last session

of Parliament will enable the education authorities to deal more effectually with these cases, as the parents may be called on to cleanse the persons and clothes of the children properly within twenty-four hours after receiving notice, and failing that the medical officer may remove a child to suitable premises provided by the authorities and there detain it until it has been "properly cleansed with suitable appliances." But it is evident that even this will be of little use unless the sanitary authority most thoroughly cleanses all the bedding and clothes at the children's homes and insists on examination of all inmates of any house where an infectious case has been found. The problem is, in fact, that of not only enforcing cleanliness, but of educating the people as to the causes of these diseases. That this is no slight task is evident when it is remembered that the popular idea is that these diseases are caused only by debility and it is not at all a rare thing in the out-patient departments of the hospitals for parents to ask for a bottle of medicine to cure scabies and impetigo. It is satisfactory to know that Dr. Ritchie, the chief medical officer of the Education Committee, is fully alive to the necessity of thus educating the parents, as is shown by the circulars on infectious skin diseases recently alluded to in this column.

WEST YORKSHIRE.

THE WORKMEN'S COMPENSATION ACTS.

There is a strong feeling amongst medical men in the West Riding that in the public interests some effort should be made to obtain an amendment of these Acts. There is a great deal of malingering and consequent loss of industrial fitness amongst injured workmen. Some of this is possibly more apparent than real. Owing to the uncertainty of the law and the possibility that he may not be able to meet the medical charges, the injured person frequently does not obtain adequate treatment. He allows his case to drag along wearily month after month until he practically ceases to take any interest in attempting to recover. Probably some contributory scheme by the workmen concerned would tend to make them take a more active interest in their own recovery. In making the award there should be some provision for the payment of medical charges. The questions of workmen suffering from partial physical disability, the necessity for the more general employment of the medical referees, unanimity amongst the medical men concerned as to matters of fact, and other allied matters, all call loudly for adjustment. The Bradford Division has appointed a committee to consider these questions and make proposals to lay before the authorities. Such action taken by those who are in touch with all the difficulties connected with the question in one of the most active industrial centres in England is sure to be productive of good.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

NORTHERN INFIRMARY, INVERNESS.

SOME time ago we drew attention to the changes in the medical staff of the Northern Infirmary, Inverness, and pointed out that the alteration in the constitution whereby one of the staff, who had served fifteen years and should have gone on the consulting staff, had been appointed for another term of years, thus blocking the promotion of the assistant members, who naturally looked for advancement to the acting staff of the institution, did not seem to be conducive to the proper working of the infirmary.

The managers held a meeting on January 29th to consider the report of a subcommittee appointed to draft a new constitution, and, while agreeing that many of the changes are an improvement on the old regulations—such as the appointment by the managers of directors who will control all the affairs of the infirmary—the changes proposed in connexion with the medical staff are not such as will commend themselves to those who have the interests of the institution at heart. For instance, the appointment of the members of the medical staff "shall only be for one year," and they "may thereafter be reappointed annually

during the pleasure of the directors." It is usual to make the appointments to the staff for five years, reappointing for further periods of five years until the holder attains the age of 60 or 65. The assistant members are in future to be appointed for three years and may therefore be appointed annually during the pleasure of the directors, but vacancies in the acting staff may be filled up by the appointment of one of the assistant members; formerly they knew that on a vacancy occurring they were sure of promotion; now, however, the directors may appoint an outside medical man to the vacancy. But a change in the constitution relating to the consulting staff is, we believe, unique in the history of hospital administration. The new rule relating to the consulting staff reads as follows: "It shall be the duty of the consulting members to attend, when possible, all consultations, and, subject to the approval of the directors, they shall have the right to operate in the infirmary. There shall be placed at the disposal of the consulting members, for patients on which they may wish to operate, such number of beds as the directors may see fit to allocate." This is an unwise rule, likely to cause friction between the members of the consulting and acting staffs. The rule as it stands is unworkable.

PROPOSED EXTENSION OF ABERDEEN ROYAL INFIRMARY.

The directors of the Aberdeen Royal Infirmary, in their report, which has just been issued, mention that, with the generous gift of £26,758 received lately from Lord Mount Stephen, they propose to increase and improve the accommodation to enable the hospital to cope with the ever-increasing demands upon it. They propose to apply the funds:

1. In erecting, in connexion with the surgical block, three new operating theatres, each with suitable surgeon's room and anaesthetic and sterilizing rooms, one of these theatres and appurtenances being attached to and opening from each of the floors on that block.
2. In erecting on Sim's Square, on the other side of Wolman-hill from the infirmary, a building to provide suitable accommodation for the out-patient department, also suitable premises to which the dispensing rooms might be removed from their present site.
3. In reconstructing the portion of the basement of the surgical block at present occupied by the dispensing rooms, so as to provide suitable accommodation for the electrical department.
4. In improvements on the premises occupied by the gynaecological department.
5. In improvements on the premises occupied by the ophthalmic department.
6. In providing for increases and improved accommodation for the resident medical staff and for the nursing staff by utilizing the space at present occupied by the casualty and out-patient department, and in certain other minor improvements.

The block of ground known as Sim's Square, on which it is proposed to accommodate the outdoor patient department, was some years ago acquired by the Primrose Trustees, the price paid for it (£7,000) being part of the £10,000 which the trustees had resolved to set aside as a gift to the infirmary. When these additions and alterations are completed, Aberdeen will have a thoroughly equipped and up-to-date hospital. The present accommodation of the infirmary is sorely taxed, especially on the surgical side, and the generous and timely gift of Lord Mount Stephen will help the directors out of their difficulty. In a letter accompanying his munificent gift, Lord Mount Stephen says:

I consider it would be little short of a calamity if what I have done for the hospital should have the effect of weakening the interest of the people of Aberdeen in the old infirmary in which I was a patient sixty-two years ago.

He has set a splendid example to all those who at any time in their lives benefited by hospital treatment, and who in the days of their prosperity should remember the institution which helped them in sickness and poverty.

THE GLASGOW ROYAL INFIRMARY.

An alarming outbreak of fire occurred on the evening of February 7th, in the front block of the Glasgow Royal Infirmary. The scene of the fire was the chapel situated on the fourth floor, and, fortunately, the damage was confined to the roof of the chapel and the dome of the building. As a precautionary measure the medical superintendent removed a number of the patients from the medical wards to another part of the building. The damage is estimated

at £1,000. The block where the fire occurred faces Cathedral Square. It was designed by Adams, and is considered to be one of the masterpieces of that famous architect. The Glasgow Royal Infirmary receives the sum of £80,000 from the estate of the late Mr. James Dick, of Glasgow, and it is reported that two other Glasgow infirmaries will receive £40,000 each.

Ireland.

[FROM OUR SPECIAL CORRESPONDENT.]

UNIVERSITY COLLEGE, CORK.

DR. J. J. CHARLES, who, for thirty-two years prior to 1907, when he resigned, had held the Chair of Anatomy and Physiology in Queen's College, Cork, has notified the authorities of University College, by which the old Queen's will in future be known, of his intention to found in perpetuity a large gold medal to be competed for in each alternate year by physiological and anatomical students. Dr. Charles's patriotism contrasts favourably with that of an Arts colleague of his who, on his death after a fifty-six years' professoriate in Queen's College, Cork, bequeathed his library and a large sum of money to a university college on the other side of the Channel.

NORTH INFIRMARY, CORK.

Dr. Charles has also intimated his desire to establish and endow a bed in the North Charitable Infirmary of the city, to perpetuate the memory of his son, Captain Godfrey E. Charles, M.B., who, after a conspicuously successful university career, entered with first place the Indian Medical Service, and was shortly afterwards appointed acting professor of anatomy in Lahore. The early death of Captain Charles on the threshold of a career of great promise caused amongst his many friends deep regret, and the sympathy of the community went out to his father in his heavy bereavement. Dr. J. J. Charles is the eldest of the brilliant sons of the late Dr. Charles of Cookstown. One of his brothers was the late Dr. T. Cranston Charles, who did much research work in physiological chemistry. Another of his brothers is Sir Havelock Charles, K.C.V.O., a former student of Queen's College, Cork, who entered with first place the Indian Medical Service, became Professor of Anatomy, and afterwards of Surgery, in Calcutta University, and in 1906 was appointed Physician-in-Ordinary to the Prince of Wales.

HEALTH OF BELFAST.

At the meeting of the City Council held on February 1st a remarkable fall in the mortality for the previous month was reported. In the corresponding period of last year 111 deaths from zymotic diseases had been registered; in this year 16; in last year from pneumonia 91, and in this year 61; deaths from respiratory diseases in general and from phthisis showed a much smaller decline. The deaths of 147 children under 1 year and of 178 above 60 were registered last year; only 126 and 128 respectively this year. The total death-rate from all causes was 20.2 as compared with 27.1 last year. A few cases of cerebro-spinal meningitis had occurred, and the renewal of the Notification Act for this disease was agreed to. These satisfactory figures help to explain the general absence of a "busy time" amongst medical men usual at this season of the year. The climatologists say it is the mild winter which Ireland has experienced, even when severe frost was reported in England; the temperance party say that bad trade means less drink, and less drink means better health; and the Health Committee are inclined to view the low death-rate as the result of their vigorous policy.

The Medical Officer of Health, in a report on some insanitary property, draws attention to an undoubted evil in the following terms:

During our inspection we observed an utter absence of personal cleanliness amongst the inhabitants of the district.

There is urgent necessity for reform amongst the people themselves in their habits; they seem practically ignorant of the benefits accruing from cleanliness.

The conditions present to our minds a large field for moral and social reform.

It has been found necessary to give 402 verbal notices for dirty houses.

DESTITUTE SICK IN BELFAST.

The eighty-second annual meeting of the Belfast Society for the Relief of the Destitute Sick, one of the oldest charitable societies in Ulster, was held at the City Hall on February 5th. The Marchioness of Londonderry presided. The society is most unostentatious, and through private information and the visiting of ladies finds out really deserving cases of destitute sickness, and gives greatly required aid. Professor Lindsay, M.D., in seconding the re-election of some members of committee, pointed out that probably one-third of the population of large towns lived in poverty, and advocated the claims of this society. Dr. Calwell seconded a vote of thanks to Lady Londonderry for presiding, and said that any society which had the imprimatur of her name could appeal without fear to the public.

Special Correspondence.

PARIS.

Professor Tuffier on the Mode of Action of Physical Agents (Radium, X Rays, and High-Frequency Currents) on Cancer.—The Population in France during the First Half of 1908.—Salaries of Nurses in the Paris Hospitals.

IN his wards at the Beaujon Hospital Professor Tuffier has submitted some patients suffering from uterine cancer to treatment by radium, which was carried out by M. Dominici. It is as yet impossible to state the results, as the patients have only been observed for four months. In one case the patient suffered from an inoperable cancer; she was curetted, and radium then applied. In a month Dr. Tuffier was easily able to operate. Microscopic examination showed that the adhesions were inflammatory and not neoplastic. It was the connective tissue, sclerosed by inflammation, which was the cause of the immobility of the uterus. Another patient who had been operated on eight months previously for cancer of the uterus returned with a recurrence in the vaginal cicatrix and the foot of the broad ligament; radium caused five-sixths of the pathological infiltration to disappear, but an induration still persisted. The cancerous nature of the growth was established by microscopic examination. In the first case an apparatus consisting of a cylindrical glass ampoule containing 9 centigrams of pure radium bromide, enclosed within a silver sheath 1 millimetre thick, and then placed inside a rubber drain 2 millimetres thick, was introduced into the cancerous uterine cavity. This apparatus furnished an ultra-penetrating radiation of 16,000 to 17,000 gamma rays. In the other cases a cloth apparatus was used, A. 500,000, the weight being 4 centigrams; the surface was enclosed in a lead capsule 1 millimetre thick, surrounded by a paper envelope also 1 millimetre thick. The apparatus was protected by a double envelope of thin india-rubber, and had an ultra-penetrating radiation of 3,500 to 4,000 gamma rays. It was applied every sixth day and left *in situ* for twelve hours each time. In order to judge the results obtained, sections were cut of the tissue treated by radium, and from these Dr. Tuffier draws the following conclusions, which are subject to modification:

1. The radiations penetrated to a depth of at least 2 cm.
2. The action of the radiations on the cancerous tissue was produced slowly; the absence of any morphological tissue modification for six or more days does not in any way imply that no action will follow later.
3. The action of the radiations was on the cancer cells and on the connective tissue framework, but not equally, for the connective tissue was less rapidly affected, the action being first and especially an elective one on the cancer cell.

The radiation can be regulated so as to cause no alteration in normal tissues, while at the same time stopping certain inflammatory processes; it does not destroy the elements of vascular connective tissue in a state of inflammatory reaction, but modifies its nutrition. The radiation can stop the development of the cancer temporarily by modifying the evolution of the epitheliomatous cells in different ways, which M. Dominici believes to be: (1) An excitation of the chromatin and of the

nucleoli, followed by the death of the cells which are the most specialized from the neoplastic point of view; and (2) arrest of the cancerous evolution of the cells which are the least advanced in neoplastic transformation. Comparing these results with those produced by the x rays, Dr. Tuffier found that the latter were powerless in dealing with subcutaneous cancers, but in ulcerated, granulating, and bleeding tumours they exercised an incontestable haemostatic action, causing cicatrization and producing an anaesthetic effect; but the healing was superficial and left the deep cancer intact. Microscopic examination of cancers treated by x rays showed that their action was specific on the cancer cell, the healing action being neither in the inflammatory reaction of the tissues treated, nor in the vascular troubles or haemorrhages. There were no arterial lesions, as thrombosis, no diapedesis but an elective necrosis of the neoplastic elements. The microscope showed that their action was very limited in depth, and that often in spite of apparent cure, active neoplastic elements were found at a depth of less than 2 millimetres from the surface treated; isolated and atrophied cells were found in the most superficial portions, but active cancer cells with karyokinesis, proof of their proliferating activity in the subjacent layers. Dr. Tuffier also investigated the method of action of high-frequency currents (fulguration), which were applied by M. Keating-Hart in five cases of inoperable cancer, once alone, and in the four other cases after ablation and as complete a curetting of the neoplastic tissue as possible. The cicatrization of the wound after the detachment of the slough seemed to be more rapid than after a simple curetting, and the cutaneous cicatrix was supple and smooth. Unlike the x rays and radium, the sparks of high-frequency currents had no specific action on the cancer cell, but acted especially on the connective tissue. The results varied according to the length of time after treatment the examination was made. Immediately after treatment, on the healthy skin, the cells of the epidermis showed absolutely no alteration, but the superficial parts of the derma showed oedema and congestion. On an ulcerated cancerous tissue the epithelial cells were exactly similar to those which had not been fulgurated, but the connective tissue which surrounded them to a depth of 1 millimetre appeared distended by serous fluid; the protoplasm of the connective tissue cells was swollen, and numbers of white cells and a few red corpuscles were present. In sections made on the eighth day after treatment at the level of the tumour covered with skin these changes were no longer visible, save that there was perhaps sometimes a little oedema of the superficial portions of the derma; the cancer cells situated below the epidermis remained in full activity. At the level of the ulcerated or abraded portions, the connective tissue of the tumour to the depth of about 1 millimetre was markedly hypertrophied, and sections made at this level showed inflammatory tissue with hypertrophied connective tissue cells, branching and anastomosing, newly-formed blood vessels, leucocytes scattered between the cells, and fibres of newly-formed connective tissue; in the midst of this connective tissue the epithelial cells remained intact, and some few of them were in karyokinesis. At the end of fifteen days the superficial portion of the tumour, forming a layer about 1 millimetre thick, consisted of adult fibrous tissue very much hypertrophied when compared with the deep layers which had not been reached by the spark. In the midst of this fibrous tissue the neoplastic cells were as it were choked and becoming atrophied. Fulguration, therefore, although it had no elective action on the cancer cell, could, by the mechanism of inflammation, eventually destroy these cells, but its action remained localized to the superficial layers; and even when cicatrization was obtained, there were, as in the case of the x rays, below it a cancer in process of evolution, though more or less hindered by the sclerosed fibrous framework. To form a definite judgement Dr. Tuffier thought it would be necessary to examine the tumours or the cicatrices several months after the application of the sparks.

In a recent number of the *Journal Officiel* appeared the statistics relating to the population in France during the first six months of 1908, compared with the same period in 1907. Heretofore these statistics have only appeared annually. The situation showed a marked improvement during the first half year of 1908. Instead of an excess of

deaths numbering 55,007 as in 1907, there was an excess of births amounting to 11,066. This result was due chiefly to the fall in the number of deaths, the total of which fell from 457,752 to 399,336; but it was due partly also to an increase in the number of births, which rose from 402,745 to 411,402.

The male and female nurses in the Paris hospitals, to the number of about 1,500, recently held a meeting at the Bourse du Travail. After listening to speeches by MM. Abadie and Duval, the assembly voted an order of the day demanding a minimum salary of five francs a day and the application of the law giving one day of rest in seven.

Correspondence.

ANAESTHETICS ADMINISTERED FOR QUACK PRACTITIONERS.

SIR,—The other day I received a communication from the General Medical Council in which was the following notice:

Any registered medical practitioner who knowingly and wilfully assists a person who is not registered as a dentist in performing any operation in dental surgery, either by administering anaesthetics or otherwise, will be liable, on proof of the facts, to be dealt with by the General Medical Council as having been guilty of infamous conduct in a professional respect.

The next day a literary friend of mine was telling me that a man whom he knew had just had his knee "put in" by a "bonesetter," and that the operation had been done under gas. It would be interesting to know who the qualified (?) practitioner was who administered the anaesthetic. I expect that this will appear one of these days. And then—?—I am, etc.,

February 5th.

NITROUS OXIDE.

THE VACANT POLICE APPOINTMENT IN LIVERPOOL.

SIR,—I think the attention of the members of the British Medical Association ought to be drawn to the flagrant attempt of the Corporation of the City of Liverpool to sweat the medical profession in connexion with the post of medical officer to the police. An advertisement appears in the daily local press of February 3rd for a medical officer to attend the members of the police force of the B division, including the members of the staff department residing within the division, and offering a salary of £60 per annum, rising to £80 after five years' service. As there are about 280 men in the B division, and the members of the staff department residing in the division are about 50, the salary offered works out at less than 4s. a head per annum. The salary of the retiring medical officer was £80, rising to £100 per annum. This reduction is being made at a time when a considerable increase is contemplated in the rates. I hope the members of the medical profession will unite to take some effectual means to frustrate this attempt on the part of the Corporation to effect a paltry economy at their expense.—I am, etc.,

February 8th.

A RATEPAYER.

SODIUM BICARBONATE IN THE TREATMENT OF CHOREA.

SIR,—In the *JOURNAL* of February 6th, p. 371, my friend, Dr. D. B. Lees, refers to my paper on alkalis in the number for January 30th. He takes exception to the statement made therein that the chief drawback to the treatment of chorea by large doses of alkalis is, "of course, the profound anaemia which such medication is liable to produce." Dr. Lees is in complete disagreement with this expression of opinion, and considers my use of the words "of course" to be especially inappropriate. In his view it is not the alkali but the rheumatic element in the choreic state which is the sole cause of the anaemia, for he holds that the poorness of blood during convalescence is in no way dependent upon the remedies which may have been used in the treatment.

Now, while I am perfectly willing to admit that rheumatism is an active cause of impoverishment of the blood, especially in early life, I maintain that an alkali given frequently in large and repeated doses also contributes materially to the same undesirable end. Of these two propositions one

is surely as well founded as the other, and I had no idea that either could be called in question. It follows then that in the treatment of chorea one may be pardoned for doubting whether in this or other occasional outcrop of the rheumatic constitution it is desirable to augment so largely the lowering effect of the complaint upon the blood by the free use of a remedy which has itself a similar depressing action. Therefore, although I am far from wishing to understate the authority with which Dr. Lees is entitled to speak on such a matter, I cannot bring myself to agree with his conclusion without much modification. In writing this I assume the accuracy of Dr. Lees's assumption that chorea is invariably associated with the rheumatic dyscrasia. This, however, is an arguable proposition and one to which I should hesitate to give my unqualified adhesion.—I am, etc.,

London, W., Feb. 6th,

EUSTACE SMITH.

APPENDICITIS AND RHEUMATISM.

SIR,—On page 186 of the BRITISH MEDICAL JOURNAL for January 16th I find the interesting statement by Dr. Alexander Haig, to the effect that in his experience appendicitis is more often due to retained uric acid than it is to mechanical causes. This must be due to the fact that the great fame of Dr. Haig brings to his office a special class of appendicitis cases, and of a sort which some of us might not classify separately as belonging to the appendicitis group.

In my own work a rough classification would place about 50 per cent. of appendicitis cases in the group in which extension of an acute colitis, the presence of irritating faecal contents, or psora traumatism lead to a swelling of the soft inner structures of the appendix within the firmer narrow outer sheath, until they suffer from compression anaemia. Bacteria then attack the unprotected anaemic tissues promptly. Such cases appear to be distinctly mechanical in origin. Perhaps 30 per cent. of my cases of appendicitis are of the class in which the appendix, undergoing normal involution, is inflamed in a chronic way through irritation of entrapped nerve filaments in hyperplastic connective tissue; 15 per cent. of my cases may be due to the congestion which goes with a loose right kidney; the remaining 5 per cent. would contain some odd or rare forms of appendix inflammation—tuberculosis, cancer, actinomycosis, and here and there a case in which the lymphoid layer of the appendix—perhaps other layers—is responding to the influence of retained uric acid in the blood.

In all of the cases of the first group, representing true infective appendicitis, it is perhaps best to operate just as soon as the diagnosis is accurately made. In the second group I have held that operation is advisable only when the "intestinal indigestion" and other reflex symptoms become too annoying. The third group of cases are apt to fade out as soon as the loose kidneys are fixed, and they seldom call for removal of the appendix. In the fourth group of cases some will require operation and some not. I have usually advised against operation in the cases in which irritation of the appendix was caused by "retained uric acid in the blood." One can separate these cases fairly well, I think, if he is accustomed to making nice diagnoses.—I am, etc.,

New York, Jan. 30th.

ROBERT T. MORRIS.

IODINE FOR STERILIZATION OF THE SKIN OF OPERATION AREAS.

SIR,—With reference to the memorandum by Major Porter, R.A.M.C. (BRITISH MEDICAL JOURNAL, February 6th, 1909, p. 332), I should like to say that the method has been adopted for some time in the clinic of Professor von Eiselsberg in the Allgemeine Krankenhaus at Vienna. The line of incision is painted over before operation with a spirituous solution of iodine, and after the stitches are inserted the painting is repeated. The object is not only to sterilize the incision area, but to prevent the invasion of staphylococci, etc., from the neighbouring unsterilized skin. When I was working in Professor von Eiselsberg's clinic in 1907 I saw over 200 operations all treated in this way, and in no case was there ever a suspicion of a stitch abscess, all the incisions being absolutely sterile. It is a measure well worth adopting in this country. With regard to the preparation of the skin, the patients are all washed with soap and water half an hour prior to the operation

and then rubbed with pure alcohol, the skin dried, and a pad of sterile gauze applied until the operation; no antiseptic dressing is ever put on. The results will bear comparison with any of our English hospitals.—I am, etc.,

H. GOODWIN, F.R.C.S.Ed.

Bovey Tracey, South Devon, Feb. 7th.

PERNICIOUS ANAEMIA AND PYORRHOEA ALVEOLARIS.

SIR,—I am surprised at Mr. C. Wynn Wigram's statement that dropping out of the teeth is clear evidence of the presence of typical pyorrhoea alveolaris at a recent date. I am under the impression that in old people the teeth not infrequently drop out from simple atrophy of the gum without any pyorrhoea, and that the same thing may occur between the ages of 50 and 60, or even earlier. I have also seen the teeth drop out without any pyorrhoea alveolaris in some cases of tabes. Not being a dentist, my opinion on the point is, however, of little value. I have therefore consulted an eminent dental colleague whose opinion I regard as authoritative; he writes me as follows:

I have to thank you for the two copies of the BRITISH MEDICAL JOURNAL containing your note on a case of pernicious anaemia, and a letter commenting thereon by Mr. C. Wynn Wigram. I had, however, read both of these communications before and had it in my mind to write something in correction of the assumption put forward that a condition of pyorrhoea alveolaris is a necessary precursor of the shedding of the teeth. As a matter of fact, the shedding of the teeth may, and most frequently does, occur as a physiological, not a pathological, process.

Atrophy of the teeth takes place: with the disappearance of the socket, the teeth first loosen, then fall out, the process not being accompanied by, or due to, any septic infection whatever, and no pus being formed. This atrophy may be a simple atrophy, or an osteoporosis. In pyorrhoea alveolaris the alveoli also atrophy, but the condition is one of osteitis rarefaciens, which is always secondary to a suppurative inflammation of the gums due to infection by pyogenic cocci, usually associated with a deposit of tartar on the necks of the teeth, often with a general oral sepsis, and sometimes with wasting diseases or other disturbances of metabolism—for example, gout or rheumatism.

The simple atrophy of the alveoli is to be regarded as a senile change, so too, as a rule, the osteoporotic, but the alveolar process may disappear prematurely, a state of affairs which has been dignified by the name of atrophial alveolaris praecox.

I must emphatically dissent from the dictum of Mr. Wigram that the dropping out of the teeth is absolutely diagnostic of the presence of pyorrhoea alveolaris at a recent date. I must confess at the same time that I have no knowledge of the "less obvious symptoms and signs" of this disease which he leaves us to infer are only recognizable by a dentist, though I am anxious for enlightenment.

—I am, etc.,

Edinburgh, Feb. 4th.

BYRON BRAMWELL.

CONFERENCE ON THE MEDICAL PROFESSION AND FRIENDLY SOCIETIES.

SIR,—Heartily as I agree with your correspondent "Anhidrotic," I feel that even the satisfactory settlement of the club question—if that be possible—would be but a half-measure.

Is it not time for the causes of the evil to be attacked and removed? These seem to me to be, at least in the main, obvious enough, yet much talk and little treatment is accorded to the matters which are mere symptoms. In my opinion, the causes are: (1) That a large section of the lay public, imbued with the spirit of the times, is consumed with desire for the cheap. These people require not an honourable gentleman who puts his patient's good before all questions of personal advantage, but a hired quack, whom they tempt to cheat them by inadequate payment, often grudgingly given, often withheld. And (2) that men not fit to enter any profession—least of all the medical—have unscrupulously employed trade methods, and have even sought to cloak their actions under the guise of philanthropy.

The education of the public may be achieved in time if we reform within the profession, and if men like Sir Thomas Barlow will speak out as he did on February 6th. For the safeguarding of the honour of the profession surely some means can be found. Could a recognized scale of charges not be drawn up by the Association as a recommendation, and could not each Branch, or, if thought advisable, a smaller district, decide upon a minimum local fee?—I am, etc.,

February 9th.

ONE WHO TRIES TO PLAY THE GAME.

THE HOME TREATMENT OF SCARLET FEVER.

SIR.—In view of Dr. Harold Kerr's summary dismissal of Dr. Milne's claim as to the efficacy of eucalyptus oil in preventing the spread of infection in scarlet fever, I should like to submit a few cases which certainly appear to support Dr. Milne's statements.

After seeing Dr. Milne's first communication on the subject I decided to try this method of inunction, but substituted the sucking of formamin tablets for the throat-brushing. In the following table are included all the cases of scarlet fever, except those removed to hospital, that I have attended since beginning this line of treatment:

Cases in House.	Children.	Subsequent Cases.	Desquamation.	Remarks.
1	3	1	0	Hands and feet.
2	2	1	0	Hands.
3	2	1	0	Hands.
4	2	4	1	Free; rubbing stopped.
5	2	3	1	Nil.
6	2	3	0	Nil.
7	2	2	0	Nil.
8	2	2	0	Nil.
9	2	0	0	Nil.
10	2	1	0	Nil.
11	2	1	0	Nil.
12	2	1	0	Nil.
13	4	1	0	Nil.

Only children who had not previously suffered from scarlet fever are included in the second column, and the parents and other adults living in the house have been entirely ignored.

I noticed in the first few cases that desquamation occurred on the parts from which the oil had been washed or rubbed off. Hence, in the later cases, I prohibited washing for five days, and ordered the hands to be covered with cotton gloves. After adopting this plan none of the cases desquamated.

It seemed to me that in this series of cases recovery was much more rapid than usual, even in those which were very acute at the onset of the attack. The only explanation I can offer is the patient's living in an atmosphere of eucalyptus vapour, which should prove an advantage in the fight against the specific organism.

Dr. Harold Kerr scoffs at the idea of an aroma killing anything—an undoubtedly ridiculous idea, an aroma being a sensation due to the presence of the vapour of some volatile substance. May not the vapour of the volatile substance be of some value as an antiseptic? Surely he does not deny that formalin vapour comes under this category?

I shall not attempt to give the explanations Dr. Harold Kerr asks for; and I hope he will be kind enough not to explain away the facts I have given on the grounds either of twelve errors of diagnosis or of twelve separate coincidences.

Finally, I should venture to suggest that Dr. Harold Kerr would be better able to sit in judgement on Dr. Milne and his methods if he gave these a trial instead of quoting authorities and asking conundrums.—I am, etc.,

Dunfermline, Fife, Feb. 1st.

J. DALGLIESH.

THE RADIIUM INSTITUTE.

SIR.—We are told in your editorial of last week that the justification of the existence of the Radium Institute lies in the fact that radium is expensive. We are also told that it is intended to charge suitable fees to those who can afford them. In other words, a monopoly is to be created for the treatment of certain diseases with funds provided

and an amount of patronage accorded which will ensure its success. May I ask if the formation of an institute on these lines is fair to those members of our profession who have devoted their time, at great personal risk and some sacrifice, to the study of radiations in general? There already exists in many of our large hospitals special departments devoted to the application of x rays, Finsen light, and electro-therapeutics in which the necessary experiments with radium could be carried out, granting that the material is forthcoming. Might I suggest that the Radium Institute find the radium, and that the work be done by the specialists connected with our existing special departments?

One might imagine, from the amount of publicity which is being given to the therapeutic effects of radium, that some new phenomena had been recently developed; but this is not the case. Sir Frederick Treves's lecture upon the subject contains nothing that is new, and that was not previously known to all those who have studied the subject. He is, however, to be congratulated in bringing the facts to the notice of the profession in a manner calculated to win their confidence. Many hospitals have already a supply of radium, and experiments have been in progress during the last six years. The Imperial Cancer Research Fund has also experimented, and many of the results obtained have from time to time been published. The reported results have certainly not been quite so successful as those quoted by Sir Frederick Treves, but the amount of radium at their disposal may not have been large enough.

That radium has a great field of usefulness in the treatment of disease I am confident, and it may effect cures where the x rays have failed; nevertheless it is unfair to decry the x rays on this ground. There is no royal road to cure any disease, and one method of treatment often fails where another is successful. The x rays have proved a useful servant to us, and I most emphatically disagree with the assertion that we have reached the limit of their power. Indeed, I am more in agreement with those who say that radium can achieve nothing which the x rays cannot do better and more quickly. The x rays may have cured many cases where radium has failed.

As an instrument for diagnosis the x rays have far surpassed the predictions of the early workers, and if surgery has not advanced as the direct result of their application it is because surgeons have been slow to take advantage of the increased power placed in their hands. In the treatment of lupus the x rays have achieved more than any other therapeutic agent, notwithstanding that in some cases they fail to produce any very marked benefit. In the treatment of ringworm and syphilis a cure can be promised with certainty. In epithelioma and rodent ulcer a cure can be brought about, but unfortunately it is seldom lasting. Warts, moles, dermoids, port-wine marks, etc., can be removed. Itching is relieved in nearly every instance, and as an analgesic the x rays have no competitor. In the treatment of cancer the x rays have proved of the greatest service; they certainly, so far, cannot be put forward as a cure, although they have a direct influence upon the growth of young cancer cells; but they relieve the pain, lessen the rate of growth, diminish the amount of discharge, enable the patients to sleep, make their lives more comfortable, and occasionally bring about as nearly a cure as can be obtained by any other method.

The scope of the application of the x rays is continually enlarging, and will continue to enlarge as our knowledge of them increases. Their action upon the blood is as yet imperfectly understood, and we have an unlimited field for research yet untrodden.

Experiments with the x rays are exceedingly costly and dangerous, and it must not be forgotten that whilst the initial cost of radium is enormous, when once obtained it is a constant quantity, whose properties only require investigation; x rays, on the other hand, have to be produced by means of mechanical and electrical contrivances, which are constantly being improved, involving an everlasting renewal and change of costly apparatus. The progress of the x rays has in the past been hampered by want of funds, and if the Radium or some other institution could help us in this matter, I can safely predict a valuable return for the money.

The analgesic properties of radium are for the most part

superficial, whilst it is in deep-seated and un-get-at-able pain that the x rays prove most useful.

I do not for one moment wish it to be thought that I in the least degree depreciate the value of radium, but inasmuch as the effects of radium are to a large extent due to its giving off x rays I contend that the investigation of these therapeutic agents should rightly be placed in the hands of those who in the past have sacrificed so much in their efforts to apply the x rays to the relief of pain and suffering.

The question has been asked, Is radium a new healing force, or merely a very powerful and penetrating caustic? It is curious that the same question was asked about the x rays. As far as the x rays are concerned, the fact that deep-seated structures can be influenced without any effect being produced upon the skin, and that changes in the blood follow their application should be a sufficient answer; and as far as radium is concerned, there can be not the slightest doubt that it exhibits properties far exceeding those of a caustic; moreover, its effects are not penetrating.

If the Radium Institute is to carry out investigations with any chance of success, it must necessarily be equipped with the apparatus for generating x rays, ultra-violet rays, high-frequency currents, etc. May we assume that these agencies will also be applied to paying patients? If so, where, may I ask, will this institution differ from an electro-therapeutic institute run for the purpose of making a profit? Whilst I heartily agree that no stone should be left unturned which is likely to increase our

knowledge concerning these valuable remedies, it must not be forgotten that radiography is recognized as a special branch of our profession, and there exists a number of medical men whose living depends upon it. I trust that the committee of the Radium Institute will keep this fact in mind when drawing up rules for their future guidance. —I am, etc.,

Birmingham, Feb. 8th.

JOHN HALL-EDWARDS.

BOYS' RACES.

SIR,—Pray extend the hospitality of your columns to the opinion of our highest medical authorities, and so save many a boy from physical wreckage in his youth or later years.—I am, etc.,

J. HERBERT FARMER,

Old Harrovians and Middlesex County Football Captain, 1886-91.

19, Portland Place, W.

January 26th, 1909.

Dear Mr. Farmer,

In reply to your inquiry, we have no hesitation in saying that we consider that school and cross-country races exceeding one mile in distance are wholly unsuitable for boys under the age of 19, as the continued strain involved is apt to cause permanent injury to the heart and other organs.

Yours faithfully,

(Signed)

LAUDER BRUNTON.

ALFRED FRIPP.

Obituary.

ALEXANDER PATTERSON, M.D., F.R.C.S.,

LATE SURGEON TO THE WESTERN INFIRMARY, GLASGOW.

DR. ALEXANDER PATTERSON, for some thirty years a leading consulting surgeon and teacher of clinical surgery in Glasgow, died recently at Draperstown, co. Derry, a property which had been in his family for many years, and to which he retired about four years ago.

Alexander Patterson was educated at the University of Glasgow, and graduated M.D. in 1854; he became F.R.C.S. Edin. in 1860, and F.F.P.S. Glasg. in 1869. In 1868 he was appointed Dispensary Surgeon to the Royal Infirmary and Surgeon to the Glasgow Lying-in Hospital. In 1872, having removed to the western part of the city, he became Surgeon to the Lock Hospital, and shortly afterwards to the Western Infirmary, then recently opened. While attached to the Royal Infirmary, he had the great advantage of witnessing the steps by which Lord Lister developed the antiseptic system. Patterson early grasped its significance, and in addressing the Glasgow Medico-Chirurgical Society in 1873, he spoke of it as ranking only second in importance in practical surgery to the introduction of chloroform. As an operator he was

both skilful and successful, remarkable for his neatness and rapidity, due, probably, in part, to the fact that he was ambidextrous. His surgical dexterity, combined with his adoption of the antiseptic system, account for the long series of ovariectomies he performed without a death, at a period when such a record was the exception rather than, as at the present day, the rule.

He was a pioneer in renal surgery, and published in 1880 what is believed to be the first case of nephrotomy deliberately undertaken for the removal of a stone from the kidney. He wrote on the treatment of aneurysm by digital compression, and on strangulated hernia, his interest in the latter subject leading him to devise a herniotome, which was a great improvement on that invented by Sir Astley Cooper. He also appreciated the

importance of fresh air at a time when the belief that warmth was necessary for surgical patients sometimes led to hospital wards being very ill-ventilated. He insisted on all the windows in his wards being kept wide open at the top day and night, and often asserted, not only that the nurses in his wards were the healthiest in the infirmary, but also that surgical patients admitted with bronchitic coughs rapidly got rid of them.

He was a man of some what austere exterior, but possessed a most genial and lovable nature, and was always delighted to help a younger man to acquire the surgical art. As a clinical teacher he had a high reputation, and his old students will agree that what they learnt from him has always remained with them. As an operating surgeon Dr. Patterson was for some thirty years one of the best known men in the West of Scotland, whose opinion was valued as highly as his operative skill was admired.

In his early days he was an enthusiastic volunteer, and always recalled with pleasure that he was one of the guard of honour formed to receive Queen Victoria at the opening of the Loch Kairine Waterworks in 1859. He had a fine collection of coins, tokens, and medals, and was well known as a collector of the works of Robert Burns.

GEORGE WATT, M.D., J.P.,

ABERDEEN.

STUDENTS of Aberdeen University in the early Seventies will bear with regret of the death of Dr. George Watt. He died from cardiac disease on the morning of February 3rd. A native of Donside, where he was born sixty-one years ago, he went to Aberdeen with the intention of studying for the legal profession, but medicine had greater attractions for him, and after being three years in a lawyer's office he entered Marischal College as a medical student. After graduating M.B. and C.M. in 1876, Dr. Watt practised four years in Yorkshire, but returned to Aberdeen in 1880, and soon acquired a large general practice; for many years he acted as one of the Dispensary Surgeons and was Medical Officer to Blairs College and St. Nazareth House. An ex-President of the Medico-Chirurgical Society, he continued till the last to take an interest in its proceedings, especially the Widows' Fund, of which he acted as treasurer. Some years ago he purchased the estate of Invernettie, Strathdon. Dr. Watt was a devoted Churchman and a staunch Conservative; he was a man of amiable disposition, ever ready to hold out a helping hand to a brother in distress; he was held in high esteem by the medical faculty in Aberdeen. He leaves a widow and daughter—an only child—to whom the sympathy of a wide circle of friends will be freely extended.

Public Health

AND

POOR-LAW MEDICAL SERVICES.

DAMAGES FOR DEFECTIVE DRAIN.

H. G. writes: A. is a medical practitioner renting a house from C., and B. lives next door. B.'s servant puts a tin down the water-closet drain, which, by causing an obstruction, brings about a bursting of the drain into A.'s cellar, which then has 4 in. of water, owing to the overflow of a surface drain that C. had neglected to put in order. The cellar walls are soaked in a foul mixture of stale water and faecal matter, and A., who had been convalescing from an illness, has a relapse due to blood poisoning. Acting on medical advice, A. closes the house and removes to other quarters with immediate favourable results. His locum tenent and servants also exhibited signs of sewage poisoning. (1) From whom can A. claim compensation for damages? (2) Would C. have ground for a claim against B. for depreciation in letting value of the house?

* (1) On the facts stated A. would have a claim on B. for damages, but the matter is complicated by reason of the cellar being already in an insanitary condition owing to C.'s default. Our correspondent before taking any action would be wise to consult an experienced solicitor, as many technical points might arise, as, for instance, the nature of the drain, and who was responsible for keeping it in repair; was the drain that burst B.'s private drain, or a drain common to A. and B.? (2) C. would also have a claim against A., but the fact that the damage might have been partly due to his own default would tend to militate against his claim.

Universities and Colleges:

UNIVERSITY OF EDINBURGH.

The following candidates passed at the January examinations for the diploma in Tropical Medicine and Hygiene:

Samuel Alexander McClintock M.B., Ch.B., Stewart M'Naughton, M.B., Ch.B., Hugh Lancelotti Sells, M.B., Ch.B.

UNIVERSITY COLLEGE OF SOUTH WALES AND
MONMOUTHSHIRE.

At a meeting of the council on February 4th, Sir Alfred Thomas, M.P., presiding, much time was given to the consideration of the financial position, and a committee was appointed to prepare a scheme for submission to the Court of Governors on February 13th. Arrangements were suggested for the award of the ten scholarships to be offered to the Cardiff Education Committee by the college in return for the increased annual grant of £400.

Mr. J. Austin Jenkins, B.A., the registrar, was appointed representative of the college on the council of the Central Welsh Board; Dr. W. E. Thomas, F.R.C.S., the Rev. J. Morgan Jones, and the Rev. H. M. Hughes, B.A., were elected, with the principal, the representatives of the council on the court of the university.

It was resolved to present an address in English and Welsh on the occasion of the Darwin jubilee celebration in Cambridge next summer.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the monthly business meeting of the college, held on Friday, February 5th, the President admitted as Licentiates in Midwifery the undermentioned candidates who had passed an examination for that Licence held on Thursday, February 4th:

Mangaldas Vibhucandas Mehta, B.A., L.M. and S., Bombay, 1908.
Kathleen Reed, L.R.C.P. and S. Edin., L.F.P. and S. Glasg., 1909.

CONJOINT BOARD IN IRELAND.

The following candidates have passed the examinations indicated:

THIRD PROFESSION EXAMINATION.—G. F. Allison, A. D. Clanchy, J. M. E. Coghlan, O. G. Connell, C. A. Farrell, J. W. Flood, F. H. Gleeson, P. Harrington, J. P. Johnston, D. J. Lyne, J. Mitchell, F. J. McManus, J. H. O'Neill, R. P. Thomson, H. Q. O. Wheeler, J. McG. Williams.
SUPPLEMENTAL EXAMINATION.—T. S. Ambrose, J. P. Carroll, M. Cahill, J. J. Cosgrove, J. P. Gimes, J. M. Marrow, P. W. O'Connor.

APOTHECARIES' HALL OF IRELAND.

The following candidates having passed the necessary examinations have been granted the diploma:

C. J. Neelan, T. B. Johnson, E. Johnson.

Hospitals and Dispensaries.

THE ROYAL PORTSMOUTH HOSPITAL.

OPENING OF NEW CHILDREN'S WARDS.

THE new children's wards of the Royal Portsmouth Hospital were opened on February 3rd by Princess Victoria of Schleswig-Holstein. President of the Portsmouth Branch of the League of Mercy. With the erection of the children's wards three of the four blocks included in the original plans of 1897 have been completed.

The new block, which owes so much to Mr. J. J. Young, J.P., Chairman of the Building Committee, are designed on the most modern principles of sanitation and hygiene. It contains two wards, one for boys and the other for girls, with 20 beds and 4 cots in each. There are also two small side wards with 2 beds in each; accommodation is thus provided for 52 children in all, as compared with 36 in the old wards. The wards have windows on every side except the north, and they will have the sun the whole day through; the area of glass is estimated to equal one-fifth of the area of floor space. The enamelled walls are embellished with inset picture panels illustrating well-known nursery rhymes executed in painted tiles procured from the Royal Doulton Potteries. The wards are fitted with their own kitchens, bath-rooms, and necessary offices. At the southern ends there are covered balconies for convalescent patients. The new wards are called the "Edward and Mary," after the children of the Prince and Princess of Wales, and the "Young" ward, after the chairman of the Building Committee. It was recalled with pride that the royal family have always taken a warm interest in the hospital, since the foundation stone of the old building was laid by the Prince Consort in 1847, and His Royal Highness and Queen Victoria became its patrons, as King Edward and Queen Alexandra are to this day. The foundation stone of the new blocks was laid in 1897 by the Duke of Cornwall and he were opened two years later by the Duke and Duchess of York.

Princess Victoria of Schleswig-Holstein was received at the hospital by the Bishop of Winchester, president of the institution. Alderman Sir George Couzens, chairman of the governing body, the Rev. W. C. Hawksley, chairman of the committee of management, and Mr. J. J. Young, J.P., chairman of the building committee, Statements as to the raising of the necessary funds, the steady growth of the hospital, and the details of the actual building of the new wards were given respectively by Mr. Young, Dr. Ward Cousins, and Mr. C. W. Ball, honorary architect to the hospital.

Dr. Ward Cousins, in eulogizing what he termed "those splendid wards," said they were up-to-date, and there had never been anything like them in Portsmouth before. They would be of enormous benefit in the treatment of the poor children. The original decision to build a hospital was arrived at a meeting held at the Beneficial Society's Hall, Finsbury, in 1846, when the Mayor (Mr. James Hoskins) presided, and on that occasion £700 was raised in the room, and 100 life subscribers were obtained. Several sites were offered by the Board of Ordnance. A contract was accepted, and on September 27th, 1847, the Prince Consort laid the foundation stone, the building being formally opened by the then Bishop of Winchester on January 22nd, 1849. Commenting on the progress of the institution during the next fifty years, Dr. Ward Cousins said that it was an old-fashioned building, but slowly, quietly, and unostentatiously good work was done within its walls, and various extensions and reforms were effected. Towards the end of the last century the wave of hospital improvement which had spread over the country reached Portsmouth, at the time of her late Majesty's Diamond Jubilee. Plans were got out for the rebuilding of the whole hospital, and in 1899 two new blocks were opened. Now they were about half-way through the new Portsmouth Hospital, which was sure to make progress and be completed.

A vote of thanks to the Princess Victoria was proposed by Sir George Couzens, and seconded by the Rev. W. C. Hawksley, after which Her Highness made a tour of inspection of the hospital.

Medico-Legal.

PUBLIC INQUIRY REGARDING A DEATH FOLLOWING AN OPERATION.

BEFORE Sheriff Laing and a jury at Aberdeen on February 4th an inquiry was held—probably the first of the kind in Scotland—in regard to the death in the Royal Infirmary, Aberdeen, of a child 3 years old. The petition set forth that "on January 6th, in the Royal Infirmary, while Alexander Mann was beginning to recover consciousness after undergoing an operation under an anaesthetic he became sick, and died from asphyxia caused by his being unable to bring up the vomited matter with which his stomach was charged."

Evidence was led to the effect that this child was a patient at the out-patient department of the infirmary. The attending surgeon considered that it was necessary that the child should come up for a slight operation on a stated afternoon. Dr. Smith, the surgeon who was consulted, stated that he gave instructions that on the day of the operation the boy should have a light breakfast, no dinner, but perhaps a little milk or beef-tee in the forenoon before bringing him to the infirmary. Dr. Smith's evidence was corroborated by the house-surgeon. On the other hand, the mother of the child stated that she got no definite instructions as to feeding, and that the boy's dinner, which she ate, was a bowl of soup, and she gave him a little beef-tee, consisted of a few pieces of beef. She further stated that the nurse in charge did not ask her what food the boy had taken that day, neither did the house-surgeon nor the surgeon who operated. These two gentlemen stated in their evidence that they did not inquire as to what food the child had taken. Dr. Danson, the house-surgeon, stated in his evidence that he administered the anaesthetic, A.C.E. mixture; the child took the anaesthetic well, and the operation was performed by Dr. Gibbist quite successfully. It lasted about eight or ten minutes, and was quite simple. About four minutes after Dr. Danson had ceased administering the anaesthetic he noticed some sickness coming on as the boy was recovering from the anaesthetic. He called for certain things, used them, and the boy recovered. Another and a much more severe attack followed, and the doctor suggested a more radical step for bringing the boy round, which was carried out in succession. The boy breathed for some time after that, and apparently had recovered, but within three or four minutes he showed signs for the third time that he was going to vomit, with the result that artificial respiration was adopted and the throat cleared out. Eventually, however, the boy became so bad that the operation of tracheotomy had to be performed. The boy vomited solid beef, and Dr. Danson took beef from his throat and from below the wound.

Sheriff Laing, in addressing the jury, said: "This case is different from the usual class of cases in connexion with the inquiries under the Fatal Inquiry Act. There was no fatal accident in the case, and the reason why the inquiry was held was that the Lord Advocate may order an inquiry into any case where death has arisen from circumstances into which he thinks it necessary there should be some investigation. The importance of the case, apart altogether from the unfortunate result which attended the operation, lay in the fact that the sudden death occurred in the Royal Infirmary. The circumstances attending the death of the child were perfectly clear. It appeared that it was necessary that some slight operation should be performed, and Dr. Smith, who was consulted by the child's mother, fixed a certain date on which the mother should take the child to the infirmary for the purpose of having it operated on. It was clearly proved that Dr. Smith gave the usual and necessary instructions to the child's mother—to see that on the morning of the operation the child should get nothing substantial to eat. To use Dr. Smith's own words, he told the mother that she should give him an aperient the night before; that in the morning he was only to have a very light breakfast, and that he should have nothing between that time and the operation unless it was a glass of milk or a little beef-tee, or some slight nourishment of that kind. Having reviewed part of the evidence, the Sheriff concluded: 'There has been nothing disclosed which in any way reflects on the administration or management of the infirmary. It is essential, of course, that an institution of the kind, within whose walls a great and noble work is being performed, should carry with it the confidence of the public at large, and I can only desire to say that there has been nothing in this case suggestive of any further action or carelessness in the way in which the operation was performed, or that reflected on the management of the infirmary in any way. A verdict in accordance with the evidence was returned.'

FEES AND EXPENSES FOR TREATMENT OF DECEASED PATIENT.

LAST week an interesting case was tried at the Tralee Quarter Sessions, in which Dr. F. G. O'Connell, Adams, and Dr. John Booth were plaintiffs, and intimately associated were the further actions of Mr. Richard Sumner, a chemist, and Miss O'Toole, the proprietress of a private hospital. The defendants were the executors of the late Mr. Hugh Burke, of Tralee, who died leaving a large estate.

Mr. Burke, who was a patient of Dr. Hayes, of Tralee, was sent by him to Cork to consult Dr. Atkins, in whose consulting-room he showed symptoms of uræmia. Dr. Atkins, on seeing him, told that Dr. Atkins sent him to Miss O'Toole's private hospital,

where for three days his condition was extremely precarious and he eventually died, on the fourth day. The executors objected to pay the medical expenses of the case unless they were proceeded against. The County Court Judge gave judgment for the plaintiffs in each case, with full costs and travelling expenses, remarking that Dr. Atkins's fee of thirteen guineas was very moderate under all the circumstances.

An interesting point submitted was whether a private hospital is entitled to charge £10 for the inconvenience caused by the death of a patient residing therein. Apparently his Honour thought so, because he allowed the greater part of the nurse's charges.

WORKMEN'S COMPENSATION CASES.

Employers' Payments for Treatment.

SULEMAN v. OWNERS OF "BEN LOMOND"—a case which came before His Honour Judge Sir Sherston Baker, sitting at Grimsby County Court on January 26th—raised a point of considerable interest to hospital authorities. According to a note in the *Law Times*, the question was whether payment by the employers to a hospital for the benefit of an injured workman could be deducted by the employers from the weekly payments made to such workman under the Act of 1906. It appeared that an Arab seaman, while engaged on duty on board the ss. *Ben Lomond*, fell from the upper to the lower deck, and sustained serious injuries to his left thigh. The authorities of the Grimsby Hospital, to which he was taken, required the owners of the steamship to guarantee the hospital payment of 14s. a week for taking care of the injured man. This the respondents did, and admitted their liability to compensate the man at 16s. 1d. a week during his past and future incapacity. They, however, deducted 14s. a week from the 16s. 1d. during each week that the man was in the hospital. His Honour Judge Baker held that the money paid by the respondents to the hospital under the above circumstances was clearly a benefit which the applicant received from the respondents during the period of his incapacity, and that they were entitled to deduct the 14s. from the weekly payments whilst he was in the hospital.

RECEIPT STAMP.

R. R. R. asks: (1) Should the assistant give a receipt for his salary when he is paid? (2) Should the assistant affix a stamp on receipt when he receives the salary account? (3) Is the receipt a lawful receipt if the assistant affixes a stamp and initials it, but fails to put on the stamp the date on which his salary has been paid him? (4) If he fails to do so what amount of fine is imposed by law on principal and assistant each? (5) If he fails to either stamp, or initial the stamp, can he not claim and recover in court the amount of salary which he has been already paid?

. The answers to our correspondent's questions are:

(1) If his principal desires to have a receipt he should give one. (2) Yes, if the amount is £2 or upwards. (3) Yes, the assistant must cancel the stamp, but is not bound to write the date of receipt of the money across the stamp. (4) The person giving the receipt without a stamp is liable to a penalty of £10. (5) No, certainly not. If an assistant in such circumstances sued for his salary a second time, his principal could not produce the unstamped receipt as evidence of payment, but the payment might be proved in other ways.

FOR COUNTERS (NEW) LONDON AND ALL OVER THE WORLD

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

OBLIGATIONS OF A SUBSTITUTE.

W. J. E. writes: A. and B. are practitioners in the same town. A. is urgently summoned to Mrs. C., who has met with an accident. He is out, however, and Mrs. A. sends the messenger on to B., who attends for A. Some months subsequently Mrs. C. sends for B. to attend her child. Ought B. to do so? B. feels that Mrs. C. might never have known him had he not attended for A., and yet if he refuses to attend her child he will undoubtedly offend her, and so very likely alienate others who it is very possible may become his patients.

. It is admitted that B. acted as A.'s substitute, and obtained the introduction to the family in that capacity; hence it would be contrary to the principles of professional ethics if a few months after he were to accept the lady's child as his patient. He must disregard the contingencies which appear to weigh with him; but, if he explains the honourable obligations under which he is placed as A.'s substitute, he will find that he will gain more than he will lose in the estimation of his neighbours.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL CHANGE OF ADDRESS.

THE offices of the British Medical Association and of the BRITISH MEDICAL JOURNAL have been removed to 429, Strand.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, London, W.C.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Attilio, London*. The telegraphic address of the MANAGER of the BRITISH MEDICAL JOURNAL is *Articulate, London*.

TELEPHONE (National).—
EDITOR. GENERAL SECRETARY AND MANAGER.
2631, Gerrard. 2630, Gerrard.

MANAGER. 2634, Gerrard.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Manager, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

We would request correspondents who desire to ask questions in this column not to make use of such signatures as "A Member," "A Member B.M.A.," "Enquirer," and so on. By attention to this request much confusion would be avoided. Correspondents are asked to write upon one side of the paper only.

WESTMORLAND asks for experience of rotagen and thyrodoxin in the treatment of exophthalmic goitre. The former is expensive and the latter is said to give equally good results and is cheaper.

CLEANING DENTAL PLATES.

B. asks how to clean a gold dental plate which is constantly covered with deposit on its palatal surface.

"The plate can be cleaned with superfine powdered pumice and Castile soap, picking both up with a damp tooth-brush. A trade preparation, "Savon Lacoste," made by Lacoste et Cie., 5, Camberwell New Road, S.E., is convenient.

LETTERS, NOTES, ETC.

A PRIESTLY FEBRIFUGE.

DR. A. P. LANGE (Couva, Trinidad) recently sent us a sample of a reputed febrifuge, prepared by a parish priest who is a native of the island. The preparation is stated to be made from native herbs. Dr. Lange informs us that it has been used in obstinate cases of malarial fever with marked success, that it has diaphoretic properties, and is mildly purgative.

The analyst's report on this specimen is as follows: It is a turbid acid liquid containing a considerable quantity of sediment; it contains no alkaloid, but a bitter principle has been extracted which is probably the principal constituent. It has not been obtained in a crystalline condition, and was therefore probably not a pure substance; but it appeared to be of glucosidal nature. It would require a rather elaborate investigation to ascertain whether this body is identical with or related to any of the ordinary medicinal glucosides. The liquid gives no indication of the identity of the plants from which it is obtained, beyond what is suggested by a pronounced odour resembling that of pimento which is observable when it is heated.

THE CAUSATION OF INGROWING TOENAIL AND THE LOCATION OF GOITRE.

DR. CHARLES H. JOY (Tamworth) writes: Surely Dr. Stephens can appreciate the difference between being "confined to bed for a week or two" and nightly rest in bed; and is it not

obvious that the pressure of tight boots includes compression of the outer side of the big toe by the adjacent toe? Dr. Stephens exultingly informs us that his patient (Fig. 2) is a tramp, and draws the inference that he therefore could not possibly have worn pointed boots. What an inference! In conclusion, I submit that we are not discussing textbooks or the salts of calcium—I refer Dr. Stephens to the opening statement in my first letter; and I respectfully suggest that when his "innate modesty revolts," etc., it is not always wise to ignore it.

AUSTRALIA FOR THE SONS OF MEDICAL MEN.

DR. RICHARD ARTHUR, President of the Immigration League of Australasia, writes that he intends to be in London in May, and that he inquires addressed to him as to agricultural colleges in Australia, at the Royal Colonial Institute, Northumberland Avenue, London, W.C., will receive attention. Information can also be obtained from Captain Collins, Commonwealth Offices, Victoria Street, S.W. As he thinks that many medical men may be considering the advisability of sending sons to farm in Australia, Dr. Arthur intends to be present at the annual meeting of the British Medical Association in Belfast.

MEDICAL FOOTBALL.

THE result of the Rugby football match between English and Irish medicals (a goal and four tries to nothing in favour of the home team) at Richmond last week came as a surprise, especially to those who were present to watch the match. The Englishmen were the ten and played the advantage of a strong wind behind them till half time, when they had only scored a single try, owing to the fine defence of the Irishmen. The first scoring, twenty-five minutes after play opened, was due to a brilliant run by Palmer. All the remaining points were scored by the home team during the last ten minutes of play. The Englishmen were the equals of their visitors in tackling and their superiors in every other aspect of the game, getting the ball out of the scrum three times out of four. Bad luck contributed in no small measure to the failure of the visitors, for on nine separate occasions before they appeared on the field circumstances had forced them to reorganize their positions. It may be hoped that a game between English and Irish medicals, now that it has once been started, may become an annual fixture.

On Saturday, at Hale End, the London Hospital added to its prestige by defeating the United Services eighteen points to nil. The victory was due to good combined play on the part of the Hospital backs and the manifest lack of combination on the part of the Services.

Guy's Hospital visited the Plymouth district, and was defeated by the latter eleven points to nil. Plymouth was playing its full side, but the hospital showed unmistakable signs of the reorganization that had had to be effected to get up a team, although it had very much more of the game than is evident from the score.

St. Thomas's played the Royal Naval College at Greenwich, and were defeated chiefly in the first half of the game, the result being two goals and three tries to the R.N.M.C., and a try to the visitors.

University College won their game against the Crystal Palace Engineers. After a keen fast game, with plenty of instances of smart tackling, the Engineers lost to the College by two goals and three tries to nil, the success of the latter being due to the play of their three-quarter backs, who exchanged the ball with such excellent judiciously that they always had a spare man on the wing to dash for the opponents' line. In forward play the two sides were equally matched.

A "STOUT" FEE.

A MEDICAL practitioner, who was attending a licensed victualler, and had brought a physician to see him, said in an undertone to the wife as they were going upstairs that the fee would be "three guineas." After the consultation, as the money did not seem forthcoming, he again mentioned the fee, which was promptly paid. The doctors then prepared to depart, but the lady of the house interposed, and asked what was to be done with the three glasses of stout, which they now saw with surprise on the table, and which she averred her doctor had ordered as they were going upstairs. She thought "three Guinness" was the fee—perhaps a not unusual mistake for a publican's wife. It was a "stout," if not exactly a fat, fee.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Eight lines and under	£ s. d.
Each additional line	0 4 0
A whole column	0 6 6
A page	2 13 4
	8 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at Postes Restantes addressed either in initials or numbers.

The Hunterian Oration

ON

JOHN HUNTER AS A PHILOSOPHER.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS
OF ENGLAND ON FEBRUARY 15TH, 1909, IN THE
PRESENCE OF THEIR ROYAL HIGHNESSES THE
PRINCE AND PRINCESS OF WALES.

By HENRY MORRIS, M.A., M.B., F.R.C.S.,
PRESIDENT OF THE COLLEGE.

MAY IT PLEASE YOUR ROYAL HIGHNESSES,

MR. VICE-PRESIDENT,

YOUR GRACE, MY LORDS, LADIES AND GENTLEMEN,—
My first duty is to request Your Royal Highnesses to accept the grateful and respectful thanks of this College and the surgical profession of England which this College represents, for the great favour you do us by honouring the memory of John Hunter, whose inheritors we are, by your presence here to-day.

We shall ever remember with great pride that you, Sir, have deigned to accept the diploma and sign the roll of the Honorary Fellowship of the College, and the graciousness of this act has been deeply accentuated by its having been performed in the presence of Her Royal Highness the Princess of Wales.

I will also venture to add that your Royal Highnesses' visits of sympathy and compassion, such as those of the last few days, to several of the London hospitals—visits which give so much gratification and delight to the patients, and so much countenance and encouragement to the management and staffs of the hospitals—tend to qualify you, Sir, for the diploma you have to-day received; for in the noblest spirit and in the best sense of the words you have thus been engaged in that most essential part of the surgical curriculum known as "walking the hospitals."

We are met in memory of John Hunter, who was born 181 years ago yesterday, died on October 16th, 1793, and is interred in Westminster Abbey.

Those who founded this oration designed that it should be expressive of the merits, not only of the said John Hunter, but also of such persons, deceased since the delivery of the last oration, whose labours have contributed to the improvement or extension of surgical science.

Two men of remarkably strong character—namely, Sir Joseph Fayrer, Bart., K.C.S.I., LL.D., F.R.S., and Mr. Timothy Holmes—died in 1907. The former, a Fellow of this College, was distinguished for his public and private services in India and at home, for the sound good sense of his teaching and practice, and for his standard work on the poisonous snakes of India. Mr. Holmes was noted for his scholarship and extensive learning, for the eloquence of his spoken and the pungency of his written language, and for his services in various capacities in connexion with this College.

In 1908 death removed three others, namely Mr. William Allingham, Mr. Reginald Harrison, and Sir Alfred Cooper. All three were men well known by their works and writings in their respective fields of surgery, and the last two will be remembered by those who knew them personally for their exceptionally genial characters and lovable natures. Mr. Reginald Harrison and Sir Alfred Cooper, like Mr. Holmes, were Vice-Presidents and members of the Council. Mr. William Allingham likewise had served for a term of years as a member of the Council.

By the death of Professor Charles Stewart, LL.D., F.R.S., who was conservator of the Hunterian Museum for twenty-three years, and who died in office in 1907, science lost a distinguished physiologist, and this College a most able officer, a skilful draughtsman, and a very lucid and admirable lecturer.

An Italian poet has feigned that at the end of the thread of every man's life there hangs a little medal or collar stamped with his name, and that when Time with the shears of Atropos has cut the thread, he throws the medals

into the river Lethe; but that about the river there are many birds flying up and down, who catch the medals, and, after carrying them round in their beaks a little while, let them fall into the river; only there are a few swans which carry off certain medals to a temple consecrated to Immortality.

Though it may be that none of the names I have mentioned have been carried by the swans to the Temple alluded to by Aristotle, other birds have secured the medals, and, sparing them from the waters of Lethe, have deposited them with the records of this College. There they will not be forgotten.

Those are rare epochs in science which are marked by distinct progress due to some particular worker like John Hunter.

Though his name is not associated with any very striking discovery like that of the circulation of the blood by Harvey, or the specialization of nerve function by Charles Bell, his influence upon many sciences was both far-reaching and profound. His contributions to knowledge in human and comparative anatomy, in the natural history of plants and animals, in vegetable and animal physiology, and in geology and palaeontology, were of such signal value that progress was made in each of these sciences through his labours. In one of his papers to the Royal Society, Hunter, in referring to the light thrown on pathology by the then recent physiological discovery of the lymphatics as part of the absorbent system, wrote: "A discovery in any art not only enriches that with which it is immediately connected, but elucidates all those to which it has any relation."

The truth of this is illustrated by his own investigations, which, by enriching physiology, illuminated the whole range of Medicine and Surgery, and may be said to have given birth to the *Philosophy of Disease*, as Pathology may well be named after what Hunter did for it.

He was the only man in England in the eighteenth century who took a really comprehensive view of the phenomena of Nature; the only great natural philosopher between the date of Sir Isaac Newton's death in 1727 and the coming of those brilliant examples of our national intellect, Erasmus Darwin, John Dalton, Humphry Davy, and Thomas Young, all epoch-makers whose works appeared immediately after Hunter's death in 1793.

There was, however, in France, an exact contemporary of Hunter, whose life work was very similar to his. This was Louis-Jean-Marie Daubenton (1716-1800), the rival of Réaumur as the leader of natural history in France; a considerable anatomist, who dissected and described 182 species of quadrupeds; a coadjutor of the great Buffon; a great authority in vegetable physiology, in mineralogy, and on fossils.

It is highly probable that Hunter and Daubenton were influenced to some extent by each other's work—Hunter by Daubenton, more particularly in palaeontology.

Sir Richard Owen has styled Cuvier "the Founder of Palaeontology," but the claim to that title really belongs to Daubenton, whose memoir on the application of comparative anatomy to the study of fossil bones was published in 1762, or thirty-four years before the writing of Cuvier on the subject.

Very different opinions concerning (1) John Hunter's early education, and (2) his method of investigation as a philosopher, have been expressed by his biographers; yet clear information is obtainable on these points.

The impression to be gathered from much that has been written of him is that he was one of the class of untaught geniuses, who have risen to the highest intellectual eminence by their own unaided powers; that up to his twenty-first year he was indolent, averse to study or to submit to being taught, idling his time in bird-nesting and low companionship, and that he finally took up the study of anatomy and entered the medical profession after failing to become, or tiring of being, a millwright or a cabinet-maker.

I am satisfied, from the evidence of extant letters written by his relatives and contemporaries, that this description is wrong in nearly every particular.

He was the grandson of Francis Hunter, who was the second son of Hunter, the laird of Hunterston in Ayrshire, whose family history goes back to the thirteenth century.

His father was the owner of a small estate at Long Calderwood in Lanarkshire, seven or eight miles from Glasgow, which he farmed himself.

John Hunter's mother was a Miss Paul, the daughter of the Treasurer of the City of Glasgow.

John was the youngest of ten children: but besides himself, only two brothers and two sisters lived to grow up. Both brothers received the usual school and university education. James, the eldest, became a writer to the Signet. William, who was ten years older than John, was celebrated as a teacher of anatomy and surgery, and a leading London physician. Of the two sisters, Dorothea Hunter married the Reverend James Baillie, afterwards Professor of Divinity in the University of Glasgow, and became the mother of the famous physician, Dr. Matthew Baillie, and also of two daughters, one of whom, Joanna Baillie, was the highly gifted authoress of the *Dramas on the Passions*, and one of the closest friends of Sir Walter Scott. The other sister, Janet Hunter, died within a year of her marriage, and immediately after John Hunter came to live in London in 1748. Her husband was a sociable, musical, but unbusinesslike young man, named Buchanan, of good family and good patrimony, who had settled in Glasgow as a partner in a large firm of timber merchants. At that date there were no upholsterers in Scotland, and high class furniture was made in workrooms in timber yards, where foreign and rare, as well as indigenous and common, woods were obtainable. It was here that John Hunter, who prided himself upon his manual dexterity, tried his hand at cabinet-making during a short visit which he paid to his sister, Mrs. Buchanan. Hence originated the statement made by his spiteful and disparaging biographer, Jesse Foot, that Hunter had served, and failed, as a millwright or carpenter.

John Hunter lost his father when in his fourteenth year, and having for some time before ceased to attend school, continued to live at home under his mother's influence, till he came to London in his twenty-first year to study anatomy under his brother William.

He was fond of games, but passed much of his time rambling amongst the woods and brags, and taking notice of every form of animal and vegetable life.

Thus, without going to school and college, and getting the same education as his two brothers, he was gaining the knowledge which he could best assimilate, and laying the foundation of his future greatness in natural science and surgery.

The constant companionship of his mother, and the example set him by his brothers and sister, Dorothea, was an education in itself. John Hunter might have said what Charles Bell¹ wrote of himself: "My education was the example set me by my brothers. There has been a good deal said about education, but they appear to me to put out of sight example, which is all in all." And speaking of his mother, Bell adds, "she was my only teacher."

One gets the impression from their biographies that the home life of both Hunter and Bell had an elevating and an educating influence, and was devoid of the superstitions and fanaticism then prevalent in Scotland.

Since the time of Demosthenes, who from his seventh year was brought up and educated by his mother, a great many men who have attained to greatness have ascribed their success to the instruction received from their mothers. Two of Hunter's most distinguished disciples, Sir Benjamin Brodie and Sir Charles Bell, did so very emphatically. Cuvier is another instance.

In reference to his lack of school and university training, it is well known that there are those to whom this routine is insurmountably repugnant, but who yet are eager in the acquisition of other forms of knowledge. To quote Sir Charles Bell again in reference to his own experience, he said: "The memory of verses, or Latin rules, without intellectual comprehension of some principles, I was incapable of. This incapacity depressed me, and it was only when in professional education I found subjects more suited to my capacities that I began to respect myself, and favourably compare myself with my fellow-students." Charles Darwin also has told us that school as a means of education was to him simply a blank. John Stuart Mill as a philosopher, Henry Thomas Buckle as a historian, and Robert Louis Stevenson as an essayist and writer of fiction may be cited from amongst many other dis-

tinguished men who had no regular school or university education.

As to the assertion that John Hunter was fond of low society, his association with the men he met at the house of his highly educated and highly cultivated brother, William, and the fact that he married Sir Everard Home's sister, a charming and accomplished woman, all tend to contradict it.

Mrs. John Hunter was very musical, and wrote the words for Haydn's (1732-1809) English Canzonets, one of which—*My mother bids me bind my hair*—is among the best known. Hunter himself was fond of art, and a collector of prints and engravings and armour.

As to what was the philosophic method pursued by Hunter as a man of science, his writings tell in no uncertain manner.

There are only two methods open to the intellect—Deduction and Induction. Deduction starts from a general proposition and reasons from this to individual cases. Induction starts from individual facts and reasons upwards to general propositions.

For example, reasoning by deduction from the major proposition, "All men are mortal," and the minor proposition which I will put thus, "Mr. Brown possesses all the attributes of man," we arrive at the conclusion that "Mr. Brown also will in time die."

Reasoning by induction, on the other hand, we first ascertain (say from reading innumerable biographies, from the records and histories of nations, from tombstones and epitaphs, and from various facts in past and present experience) that every one who has lived has died; and then we conclude that not only will Mr. Brown himself die, but that all Brown's family and all the families of Brown, of Jones, and of Smith, etc.—in fact that all men are mortal, notwithstanding the miraculous disappearance of Enoch and that Elijah "went up by the whirlwind into the skies."

Did time permit I might illustrate the difference between deduction and induction by other but less simple instances than that I have just given, and at the same time show the difference between the Scottish and English national methods of inquiry—for example, between Cullen and Hunter in their investigation as to whether all animal matter is originally vegetable matter; or between Hutton and William Smith, who respectively were the founders of Scottish and English geology; or, again, between Watt and Cavendish, who at the same time discovered, Watt by deduction and Cavendish by induction, that water is the component of two gases.

Of each of these instances, it may be truly said that the inductive philosopher (the Englishman) established the facts, and the deductive philosopher (the Scotchman) established the ideas.

Deduction and induction have for the most part been employed separately; but by a few investigators they have been combined.

In the history of the world, there have been three great intellectual movements, leading to three great schools of philosophy, namely, the philosophy of Antiquity identified with Greece, Scholasticism identified with Charlemagne and France, and the New Philosophy which is of English birth and identified with the name of Francis Bacon.

Excepting the philosophy of Aristotle which was largely inductive, the first two were chiefly deductive. The Baconian is known as the New Inductive method.

In reviewing the intellectual movement of the eighteenth century in England, Scotland and France, in its bearing on Hunter and his work, we find that each country adopted one of the two philosophic methods as the national method.

To understand this movement better, it would have been well, had time permitted, to take a brief glance backwards at the philosophy of earlier ages.

Up to the end of the fifteenth century first Greek Philosophy, and then Scholasticism had monopolized men's thoughts; but during those two thousand years and more, they had done nothing to mitigate human suffering, nothing to advance the public weal, nothing to extend the empire of man over the material world. Indeed the application of science to useful practical ends was deemed by the old Greek philosophers to be unworthy of men of learning, degrading and debasing to philosophy, and insulting to philosophers.

Scholasticism, which was a blend of Christianity and Paganism, an "ill-starred alliance between the old philosophy and the new faith," was in reality the logic of Aristotle associated with the teaching of the Church, and by it Reason became subject to Authority, and was made the mere handmaid of Faith.

As men's interests ceased to be centred in ecclesiastical disputations, and their attention became by degrees directed to Art, Science, and practical discoveries, they looked about for some one who would lead them to the dawn of a new Philosophy.

This leader was discovered in Bacon, who propounded a philosophical system essentially new, and differing alike both in method and object from that of the Ancients, and that of the Mediaevalists or Schoolmen.

Bacon described with scorn the uselessness of the Philosophy of the Platonists, the Peripatetics, the Stoics and the Epicureans. Equally he scouted the system and dogmas of the Schoolmen.

Whilst disclaiming to be himself the founder of a sect or school, and fully foreseeing that his method was by no means perfect, he gave a new and powerful impulse in a direction diametrically opposed to both the Greeks and the Scholastics.

Some who have never studied his works seem to entertain a very incorrect idea as to what it was Francis Bacon really did for science. Of course he did not invent Induction. The inductive method has been practised ever since the world began; by every infant before weaning, by every new-born mammal as it learns that it will get milk from its mother, not from its father; by every farm labourer who finds by experience that he cannot gather grapes from thorns nor figs from thistles, and that if he sows tares, he will not reap wheat or garner barley. We are all employing the inductive method daily; and many who have never read the rules laid down in the *Novum Organum* are conducting the process as well as or better than many who have.

Bacon's great merit is that he "led forth the sciences from their house of bondage"; that he directed the minds of men away from mere verbal disputations to the discovery of truth by observation and experiment; that he incited men to develop the industrial arts and to acquire knowledge and apply it "to the glory of God and the relief of man's estate."

The chief cause of this great reformation in Philosophy was the great reformation in Religion.

THE INTELLECTUAL MOVEMENT IN ENGLAND.

In England that enlightened scepticism and spirit of inquiry which in religion conduced to toleration, in politics to freedom, and in physics to natural science, came to the front in the sixteenth century with the Reformation, increased with the Rebellion of 1645, and was confirmed by the Revolution of 1688.

The Reformation dissipated the notion of the infallibility of the Church. The history of different countries shows that as long as the governing power was in the hands of ecclesiastics, there was no toleration in Religion and little or no advance in Science. It was in England during the reign of Queen Elizabeth that Government for the first time in any European country was carried on without the active co-operation of ecclesiastical authority; and it was also during her great reign that there began the growth of that splendid literature which was to stimulate and increase the national spirit of liberty and inquiry, and to spread its influence, in a generation or two later, first over France, then throughout Europe.

During the first half of the seventeenth century, which was a period of great superstition, there was an effort to reverse the enlightened policy of Elizabeth. The influence of this on works of learning is well illustrated by the two books of Sir Thomas Browne. His *Religio Medici* was published about 1634. In this book the author exhibits a superlative degree of credulity, expresses his belief in witches, and declares his willingness to assent to a proposition all the more because of its improbability, and his readiness to believe in a thing in proportion to its actual impossibility. But twelve years later (1646), when the Civil Wars of the Rebellion were raging, and men's intellects were becoming more and more independent of authority, Sir Thomas Browne's second book, *Enquiries into Vulgar and Common Errors*,

appeared, and proved to be a systematic and elaborate attack upon most of the superstitions then prevalent. The striking inconsistency between these two works by the same author marks the growth of the vast social and intellectual changes which culminated in the overthrow of ecclesiastical intolerance and political persecution.

During the Commonwealth and after the Restoration came an increased desire for knowledge. The period following the Revolution of 1688 forms one of the most important periods in the history of the world, because it was then, and in this country, that the human intellect was completely freed from subjection to authority; and it was then, and in this country, that the triumph of liberty over despotism, and of reason over blind and enforced credulity was permanently and completely accomplished.

The suppression of superstition was further aided by the earnestness with which the physical sciences began to be cultivated during the Commonwealth, and after the Restoration.

The Royal Society was established in 1662, and Robert Boyle (1626-1691), who adopted the views and method of Bacon, was making discoveries of the very first importance.

When Hunter arrived in England, he came amongst a people deeply imbued with the Baconian spirit, for if Harvey, Hobbes, and Newton be excepted, all English scientists for a hundred and fifty years after the death of Bacon, in 1626, were eminently inductive.

Newton, who was born sixteen years after Boyle, had been dead twenty-one years when Hunter came to London in 1748; and the only giant mind in England to be likened to Hunter was Edmund Burke (1728-1797). The reflective and philosophic statesman who resembled him in the power of his intellect, in his marvellous capacity for thinking, and in his conception of general principles based on long considered ideas. Hunter's role was the philosophy of Life and Nature; Burke's, the philosophy of Civilization.

Though during Hunter's life there was no one in England pursuing science who was at all comparable with himself, or with the great Scottish and French philosophers and scientists then living, still the period covered by Hunter's residence in London was one of great national brilliancy and renown in many branches of learning and culture, despite the depths of political and commercial degradation into which the country fell owing to the taxation of America, and the American war and its consequences.

The British Museum was founded in 1753 through the collections made by Sir Hans Sloane being purchased by the Government on his death.

Sir Hans Sloane followed Sir Isaac Newton as President of the Royal Society. Like Hunter, he was led to study medicine owing to his intense love of natural history. He was the first person in England to attempt to form a museum; and it is interesting to note that the British Museum, the Glasgow Museum, and the unrivalled Museum in this College, owe their existence to collections made by London medical men of Scottish extraction, namely Sloane, William Hunter, and John Hunter respectively.

In Literature and Art the eighteenth century was very illustrious. The Royal Academy was founded in 1768 at the instigation of Benjamin West, a Pennsylvanian Quaker, who startled the Italians by likening their Belvidere Apollo to a Mohawk warrior, and is said to have painted 400 pictures for King George III. With West, three other artists were associated in obtaining the Charter of the Royal Academy, one of them being Penny, the son of a London surgeon, who was made the first Professor of Painting. Dr. William Hunter was appointed the Professor of Anatomy.

It has been said by one of the biographers of Sir Joshua Reynolds that there centred round him as the first President of the Royal Academy a "surprising and splendid constellation of genius, such as never before his time, and never since, illumined this country."

Reynolds lived opposite John Hunter in Leicester Fields, now Leicester Square, and his genius as an artist has pictured for all times, on the canvas suspended behind me, the thought-inspired features of the famous surgeon.

"The Marriage à la mode," the "Rake's Progress," and the other "pictorial sermons," as they have been called, of Hogarth; the "Blue Boy," the "Celebrated Duchess,"

and the grand landscapes of Gainsborough; the character portraits of Lady Hamilton by Romney, and probably some of the earlier paintings by Lawrence and Hoppner, must have been known to Hunter. So, too, the works of West, Cosway, Richard Wilson, Opie, and others of less importance.

Now, for the first time in its history, this country produced genius enough to establish its claim to the honourable distinction of having "an English School of Painting."

Bartolozzi, the Florentine, settled in London in 1764, and for forty years was occupied here in engraving pictures—his reproductions being as a rule more beautiful than the originals.

Angelica Kauffmann, too, was delighting Londoners by her sentimental pictures, astonishing them by her cold-blooded and unsentimental marriages, and decorating with pseudo-classic paintings the interiors of houses in the Adelphi and of mansions elsewhere, built by the brothers Adam.

Hogarth, Edmund Burke, Samuel Johnson, Oliver Goldsmith, David Garrick, Sterne and others, all friends of William Hunter and his brother John, were meeting daily at the Literary Club, the Turk's Head, or Reynolds's house.

Fielcing, having published *Tom Jones* (1749) and *Amelia* (1751), was annoying Richardson by his burlesque of *Pamela*, and worrying the Government and the Lord Chamberlain by his satires on bribery and the elections.

Smollett's *Roderick Random*, published in 1748, may have been read by Hunter during his first journey from Scotland to London.

The Rev. Laurence Sterne created a great popular success by the gross innuendoes and indecencies of *Tristram Shandy*; and the prim little Fanny Burney (*Madame d'Arley*) became famous as a novelist of irreproachable propriety.

"The Tragic Muse"—Sarah Siddons—had all but drawn tears from Hunter's eyes, and David Garrick as "Felix" in *The Wonder: A Woman Keeps a Secret*, must on some occasion or other have made him laugh until he sobbed.

Pope and Swift and Sir Robert Walpole died when Hunter was 16 or 17 years old.

Alexander Pope was a friend of Cheselden, and Cheselden was Hunter's first surgical instructor.

In this way, through Cheselden perhaps, or perhaps from hearing the poems read aloud when a boy at home, Hunter must, I think, have been influenced or inspired by Pope. The *Essay on Man* was published in 1734, and it is impossible to read some of Hunter's statements, or to follow his lines of thought, without being frequently reminded of passages on Nature, and the Universe, and the relation of man to the rest of the universe, which that poem contains.

Lastly, as a collector of prints, pictures, weapons and armour, et cetera, Hunter probably encountered that personification of affectation—Horace Walpole—in some of the curio shops or sale rooms of the town, when Walpole was hunting for oddities and rarities to add to the motley collection for which he was notorious. Collecting was becoming quite a fashion of the time.

THE INTELLECTUAL MOVEMENT IN SCOTLAND.

The intellectual movement in Scotland differed widely from that in England in the seventeenth and eighteenth centuries.

After the passing of the Acts of 1707 ratifying the Union of Scotland and England, good roads and canals connecting the chief towns and districts were made, and manufactures and commerce were promoted. Hence it happened that just about the date of Hunter's birth, Scotland for the first time in her history, produced two classes of enterprising and thinking men, whose aims were essentially secular, namely an industrial class, and a philosophical class.

During Hunter's early manhood, commercial and manufacturing prosperity had fairly set in, and philosophers and scientists of the very highest eminence were beginning to make the name of Scotland famous by their labours.

The number of original thinkers in Scotland in the eighteenth century is the more noteworthy, because in all the previous centuries the country had only produced two authors whose works were of the least merit, namely,

Buchanan (1506-1582), the Scottish historian and the greatest Latin scholar of his time; and Napier (1550-1617), the inventor of logarithms.

But the most striking fact about Scotland in the eighteenth (and the first half of the nineteenth) century was the existence of so many philosophers, and the creation of a noble and enduring literature, at a time when the Scottish were the most priest-ridden and superstitious people in Europe, not excepting even Portugal and Spain.

Besides the influence of the Scottish Kirk, another cause of the continuing ignorance and superstition of the people was the national method of inquiry. Centuries of ecclesiastical supremacy had influenced the nation in favour of the Theological Method of reasoning; and as the Church required the acceptance on faith of general principles and dogmas, and regarded it as heresy to doubt or question, this method was necessarily the deductive. Induction under such conditions is impossible. Paley, and the authors of the *Bridgewater Treatises*, and many essayists tried it, and failed.

When, therefore, the ablest minds in Scotland directed their thoughts and attention to philosophy and science, they without exception employed the deductive system with which they had been made so long familiar.

Thus it was with Hutcheson and Reid in metaphysics; with Adam Smith and Hume in political economy and history; with Black in physics and chemistry; Cullen in pathology; Hutton in geology; and Leslie and Watt in chemistry. In all branches of science it was the same. All the discoveries made by Scotsmen concerning both the inorganic and the organic world were made by the deductive method.

THE INTELLECTUAL MOVEMENT IN FRANCE.

As there is reason to think that Hunter was acquainted with the scientific work going on in France, notably that of Daubenton, and as Hunter's work was not without effect on some of the great French scientists, such as Cuvier and Bichat, I propose to examine very briefly the intellectual movement in France just before and during Hunter's lifetime.

The spirit of intellectual progress for which France was celebrated during the age of Richelieu and Descartes in the first half of the seventeenth century did not continue. In the second half of that century, and during the rest of the reign of Louis XIV, it was thwarted and delayed by the despotic and protective spirit of government, which was an early but a weighty cause of the French Revolution; just as liberty and reform in England were checked by attempts in the first half of the seventeenth century to suppress the popular will, and to reinstate in power the Catholic clergy.

Immediately, however, after the death of Louis XIV. in 1715, the state of the popular mind in France, which was thirsting for inquiry and hungering for liberty, was as favourable to the reception of the Baconian system in that country, as the popular desire for political and intellectual freedom in England had been in the seventeenth century.

When, therefore, in spite of the natural vanity of the French people during Louis's lifetime, the eyes of France turned after 1715 to England as the only country where liberty was known, nearly every Frenchman of eminence in literature and in medical and other sciences either visited England or learnt the English language; many did both.

Voltaire, Diderot, Buffon, Montesquieu, all took part in introducing English literature and English philosophy into their own country.

During the second half of the eighteenth century many of the best intellects in France were directed to physical science. A hundred years before, Descartes had made it a fundamental principle of his philosophy that we must ignore the knowledge of the external world—that is, of Nature—and must depend on "thought." Now, Helvétius, the most celebrated French moralist, and Condillac, the most celebrated French metaphysician of their period, said, "We owe the whole of our knowledge to Nature." It was this latter view which led to the discovery of more new truths in science by Frenchmen between 1750 and the end of the eighteenth century than had been made in all previous periods put together. The names of Lavoisier,

Foucroy, Berthollet, Fourier, Buffon, Daubenton, Cuvier, and Bichat bear testimony to this.

The vast discoveries which were being made roused general interest and curiosity in France. Some acquaintance with Science came to be considered essential to a good education. Lectures in all branches of science drew together persons of the highest rank as well as of the several classes below them. Women of fashion attended lectures on chemistry, geology, mineralogy, physiology, and anatomy. Antoine Petit's lectures on anatomy (commenced in 1768) were delivered before overflowing audiences. Cuvier² tells that the anatomical descriptions which Daubenton wrote for Buffon were to be seen on the toilet tables of ladies. Oliver Goldsmith, who was in Paris in 1755, remarks with surprise that he saw "as bright a circle of beauty at the Chemical Lectures of Rouelle as gracing the Court of Versailles." It was the same at the public séances of the Académie Française in 1779, and at Foucroy's lectures on Chemistry in 1784.

Such was the condition of the intellectual life in France, and particularly in Paris, during the latter half of Hunter's career.

The same spirit prevailed in this country. The English democracy had just begun to enter eagerly into political life. There was also a great increase in the general desire for knowledge, and this demand was augmented by the very steps taken to satisfy it. Now for the first time the public at large took some interest in the cultivation of the fine arts, and in 1760 was held the first public exhibition of pictures by English artists. It was during the eighteenth century that booksellers first started shops in the provinces, and that circulating libraries, and periodical reviews were first introduced. The publication of the proceedings in Parliament, against which the last standing order was passed in 1728—the year of Hunter's birth—and concerning which the Lord Mayor and an Alderman of the City of London were sent to the Tower in 1771, became an established parliamentary institution from 1772. Before the second quarter of the eighteenth century printing establishments were almost unknown in provincial English towns, and printing presses were only by degrees being set up in country towns in the latter half of the century. It was in the eighteenth century also that the earliest systematic attempts were made in England to popularize the sciences by lectures, to spread knowledge of physical truths through the medium of encyclopaedias, and simple treatises, and to give enlightenment by means of public addresses on such subjects as political rights of the people. It was in the latter half of the same century that Sunday schools, reading clubs, and debating societies first came into existence.

This desire to learn, and this rapid and widespread diffusion of knowledge amongst the peoples of France and England, were in large measure attributable to the fact that both the French and English national philosophical method was Induction. The condition of the Scottish people at the corresponding period was in marked contrast.

By comparing countries whose national system is Deduction with those whose national system is Induction, it is abundantly proved that knowledge is never widely diffused amongst a people by the deductive method, which begins with ideas; but that it spreads by means of the inductive process, which begins with facts. The deductive process, by dealing with abstract ideas, appeals to the thinking faculty and not to the senses; and as ideas are more difficult to grasp than facts, and as there are more good observers than great thinkers, deduction influences the popular mind much less than induction. Hence it was that the Scottish people did not seek enlightenment, and were content to continue in subjection to theological authority; hence it was that in England the overthrow of Scholasticism (that is, of the purely syllogistic philosophy of the Middle Ages) by the Baconian system, was followed by the general extension of knowledge and trade; and hence it was that in France in the seventeenth century the deductive philosophy of Descartes, and the Cartesian philosophers, did not lead to the general instruction of the people; whereas in the eighteenth century, after English literature, English opinions, and the philosophic views of Bacon and Locke were introduced into France

by Voltaire and others, knowledge spread rapidly amongst all classes of the French people.

With increase of knowledge came unhappily a feeling of revenge for the political and social wrongs they had suffered for generations; and the French mind, bent on obtaining freedom, was fired by a deadly determination to resist oppression and defy absolutism which finally culminated (in 1789) in the revolting cruelties of the greatest and most ghastly Revolution the world has ever known.

On October 16th, 1793, John Hunter died suddenly when attending a Board meeting in St. George's Hospital. On the same day and about the same hour Marie Antoinette was beheaded in Paris.

HUNTER'S METHOD OF INQUIRY.

The study of Hunter's works shows that he combined to an exceptional degree the two philosophic methods, deduction and induction.

There is no evidence that Hunter studied formal logic any more than Latin and Greek.

He was essentially a thinker rather than a scholar, yet an experimental philosopher rather than a metaphysician.

But Hunter saw that for a complete scheme of knowledge deduction and induction are supplementary to each other; and when the time comes, if ever it does come, when all the intellectual resources of man are fully developed and perfectly co-ordinated, then these two methods of reasoning will no longer be regarded, as they now often are, as hostile to one another, but will be combined in a single system.

Though a great inductive philosopher Hunter employed the deductive method very largely, especially in pathology. He reasoned downwards from premisses and hypotheses which he deliberately invented, and in doing so arrived at conclusions, sometimes unproven, sometimes inaccurate, sometimes only approximately correct.

Still, though it is true that some of his doctrines have had to be modified, some even set aside altogether, yet on the other hand it is astonishing how many of his speculative conclusions, both in physiology and pathology, formed at a time when microscopes were very inferior and chemical science was in a backward state, have been confirmed by his successors working with much better instruments and with additional and very superior aids to research. Thus did his genius often outstrip facts and anticipate discoveries.

His employment of the inductive method is illustrated by his attempt to explain congenital defects by a reference to transitory structures, and the metamorphoses of foetal life, as in the case of congenital hernia, which arises from the failure of the peritoneal process to become shut off from the peritoneal cavity. Other instances of his use of induction are his scheme for the classification of monstrosities, based on the disposition which every species of animal and every part of an animal body has, to deviate from nature in a manner peculiar to itself; his instructions to Jenner, as to how he should ascertain whether colour-blindness is due to a general defect, or to a failure to appreciate the usual impressions made by primary colours; his careful and patient anatomizing of so many hundreds of different species of animals and of so many animals of the same species; his numerous observations of plants; and his untiring investigation of the diversities of structures and organs in order to arrive at accurate conclusions as to what structures and organs are necessary for the performance of different functions.

As a result of these dissections and observations, he pointed out the conditions which characterized groups of animals, classifying them according to their hearts, their nervous systems, their stomachs. In this he anticipated Cuvier.

Following the induction method he trusted to nothing but his own observations, and to testing his ideas by the most varied and exact experiments. His *Treatise on Bees* is an admirable illustration of this.

Yet, in making inquiries, before drawing his conclusions he is neither prodigal of facts, nor wasteful of experiments. In reference to Swammerdam's minuteness of description of the particular structure of bees, he says that minutiae as such should be avoided, that they are only of value in so far as they elucidate principles; that notice need not be taken of things that are common to a bee and to other

insects, "but only of its peculiarities which distinguish it from all others (animals) and constitute it to be a bee."

Hunter in his *Observations on Digestion*, when criticizing Reaumur and Spallanzani, remarks: "I think we may set it down as an axiom that experiments should not be often repeated which tend merely to establish a principle already known and admitted; but that the next step should be, the application of that principle to useful purposes." And then he goes on to say: "But the application of principles requires more than simply the knowledge of the principle itself, and therefore those who cannot reason from analogy, or draw general conclusions from a few convincing facts, and who require to have every relative conclusion or inference proved by experiment, must be pleased with Spallanzani; but he must tire even those whom he informs and much more those who read his works in expectation of something new."

He made great use in practice of analogy and comparison, of resemblance and of difference. Many arguments and inferences drawn from analogy occur in his writings, some of them amounting to the most perfect induction, but others, it must be acknowledged, leading him into error. Fallacies of analogy are to be found in his *Treatise on the Teeth*—for example, he concludes from his experiments with madder on the teeth as compared with others on bone, that the teeth have neither a vascular supply nor absorbents. Again, he argues from the existence and use in carnivora of canine teeth, to their use in man, as organs for tearing and the prehension of food; thus ignoring or overlooking the fact that canine teeth are far more developed in some animals which are exclusively frugiferous.

Some of his analogies are indeed mere conjectures—for example, he infers that the bionspids are less useful than either the incisors or the molars, and he attempts to support this by saying, "in most animals, so far as I have observed, there is a vacant space between cutters and grinders."

It was chiefly by induction that he concentrated the scattered facts of comparative anatomy, and thereby advanced the progress of physiological science.

But a considerable part of his pathology also is based on the inductive process.

Notwithstanding his vast achievements in physiology, he was even greater as a pathologist.

If it be remembered what pathology was before his own time, it must be admitted that in this science Hunter remains without a rival. It is in this science especially that his depth of insight, his profundity of thought, and his comprehensiveness of view mark him out as a genius.

With Hunter, pathology included the laws of disease, not only in man, but in the whole of the animal and vegetable kingdoms. His outlook was even more comprehensive still, for it embraced not only the whole of the organic world, but the deviations from the typical form in the inorganic also.

In the study of the obscure phenomena of disease there is more scope for speculative ideas than for experimental research, at any rate for the forms of research which were possible in Hunter's day. It is therefore in his pathology much more than in his physiology, that Hunter employed the deductive method.

Thus he lays it down "as an axiom that two processes cannot go on at the same time in the same part of any substance." Two different fevers cannot exist in the same constitution; nor can two local diseases be present in the same part at the same time. Such names as *rheumatic gout*, which imply a combination of two diseases suggest a possibility of a union which according to Hunter's principle cannot exist.

Again, in his treatise *On the Blood, Inflammation and Gunshot Wounds*, he adopts the principle, that the specific qualities in disease tend more rapidly to the skin than to the deeper seated parts; and he regards this as a law of Nature, similar to the principle by which vegetables always approach the surface of the earth.

The whole chapter on Sympathy in his *Principles of Surgery* is full of deductive reasoning.

The doctrine of Health and Disease,* as explained by him, in his *General Principles of the Blood*, as well as in his *Principles of Surgery*, illustrates his desire to build arguments on principles which he spontaneously assumed.

Still another instance of deduction is his reasoning from the hypothesis that the immediate cause of action is the same in both animals and plants, but that whilst in animals there is a greater quantity and variety of motion, in plants there is more real power. He illustrates this difference by the horse and the vine. The vine can raise a column of fluid five times higher than the horse's heart can do, the energy or power of the animal being weakened by being directed to several different purposes.¹⁰

Starting with the idea that the capacity of action both in animals and in vegetables is of three kinds, he hoped by studying every inanimate to action—in reference to the power as distinguished from the quantity of action—that he or his successors would be able to arrive at fundamental truths as to the principles of organic motion.

In his *Treatise on Venereal Disease* his arguments are based upon the too hasty generalization that affections which admit of cure without the use of mercury are not venereal. He thus made the remedy the test of the disease, and sought to substantiate this preconceived idea by facts.

His attempts to prove that monsters are formed as monsters from their very beginning supplies another example of his use of deduction.

Through following the deductive method, Hunter neglected to take account of those "predisposing causes" of disease which could only be generalized from observation, and to which his English contemporaries who were inductive pathologists attached great importance. Hunter, indeed, denied the existence of "predisposing causes."

When reasoning deductively he so much relied on his premises that he sometimes refused to accept any evidence by which they were impugned. In fact, when using the deductive method, he had the failing of all deductive reasoners of not placing full confidence in facts.

In his inductive investigations, however, he never disguised or perverted facts to make them tally with his hypotheses. Instead of endeavouring to render facts and theories consistent with one another, when they evidently were not, he would adhere to his hypothesis without blinking the facts. Thus he asserted that teeth are extraneous bodies without either circulating vessels, absorbents, or nerves, but when after transplanting teeth, he thought he had established the fact that they were "capable of uniting with any part of a living body," he explained this power of uniting by attributing to teeth what he called a "living principle."

His "Croonian Lectures" ¹¹ on motion contain admirable examples of his employment of the combination of deduction and induction.

Buckle in his *History of Civilization* (vol. iii, pp. 432-5) attempts to explain the intimate union of deduction and induction in Hunter's intellect, by the fact that he was born and remained till his twenty-first year in Scotland, and afterwards passed the rest of his life in London, where he became socially and intellectually a native of England. "Hence," says Buckle, "the early associations of his mind were formed in the midst of a deductive nation, the later associations in the midst of an inductive one. The country of his birth made him deductive, the country of his adoption made him inductive. As a Scotchman he preferred reasoning from generals to particular facts; as an inhabitant of England he became inured to the opposite plan of reasoning from particular facts to general principles." And Buckle adds, "I make no doubt that one of the reasons why Hunter, in investigating a subject, is often obscure, is that on such occasions his mind was divided between these two hostile methods."

Buckle's line of argument is here purely deductive, and capable of being thrown into three or four strictly correct syllogisms—correct, that is, as to figure of syllogism, but not as to the ideas on which they are founded. Before accepting or rejecting Buckle's explanation, however, we must consider the premises on which he bases his conclusion. Like many deductive reasoners, he assumed the truth of his major premiss without having examined the facts on which it rests. He, an Englishman, has argued like the Scotch he describes; his logic being good if we concede the general propositions from which he starts.

But can we concede them?

Is it true that philosophers who have passed their youth among a nation whose method is deductive, and their manhood among a nation whose method is inductive—

or vice versa—have their minds divided between these two hostile methods, and, in consequence, are often obscure in their investigations?

The conclusion will be proved to be false if it can be shown that a philosopher may pass his youth in a country without ever coming under the influence of the national philosophic method.

This was the case with John Hunter; he never did come under the influence of the ordinary Scottish teaching. In Scotland the clergy had the control of all centres of education, both public and private, throughout the country. They directed what should be taught, and how it should be taught, not only by village schoolmasters and masters of grammar schools, but by the professors in the universities, and even by private tutors. Had John Hunter continued at school and proceeded to a Scottish university, he would of course have come under the influence of the deductive method.

But even if his education had been of the usual Scottish type, it does not follow that he would have adopted the Scottish philosophical method. His two brothers, James and William, who did receive such an education, did not adopt it; not even William, who was a resident pupil for three years, and a lifelong friend and correspondent of so thorough-going and so able a deductive reasoner as Cullen.

The courage shown by John Hunter when a boy of 12 years old, in a cottage scene described by his niece, Joanna Baillie, justifies the assertion that he was not imbued with the clerical teaching and superstitions prevalent at the time in Scotland. In the eighteenth century the most popular divines in Scotland, as well as the clergy generally, taught that Satan frequently appears clothed in a corporeal substance, and that he seized persons and carried them away in the air. When the preacher mentioned the name of Satan, the church resounded with sighs and groans, and the congregation were petrified with awe as they listened with gasping breath and hair standing on end. Such impressions were not easily effaced. Images of terror accompanied the ignorant people to their homes. No wonder, therefore, when a ghost in form of the devil appeared, whilst Hunter was chatting in a neighbour's cottage, that the cottagers, educated after this manner, were stricken motionless with fear, whilst young Hunter, brought up differently, attacked and drove away the apparition with the fire-logs.

The second statement made by Buckle is that the conflict in Hunter's mind between deduction and induction darkened his understanding. I can no more accept Buckle's explanation of the occasional obscurities in Hunter's utterances than Buckle could accept Otley's, namely, that they resulted "from a deficient education." I agree with Buckle that a deficient education no more makes a man obscure in his statements than a good education makes him lucid. With educated and uneducated alike, the power of clear expression depends on clearness of thought. When Hunter is obscure it is either owing to the complexity of his subject, or to his own mind being in doubt.

The adoption by Hunter of both methods—Deduction and Induction—was, in my judgement, the result of two causes: (1) the natural scope and bent of his mind, and (2) the nature of the subjects to which he devoted his life.

Induction is largely the method required for the profession he chose. Locke and Sydenham had left it on record that in their opinions the medical sciences to be properly pursued, ought to be approached by the Baconian method; and Hunter was one of a family, several members of which showed a great leaning towards and a marked aptitude for these sciences.

James Hunter gave up his profession as a barrister, and William, who was to have been a clergyman, abandoned the Church for Anatomy, Surgery, and Medicine; and John of his own free will, went directly into the medical profession. Their sister's son, Matthew Baillie, became the celebrated London physician and pathologist, whose medallion portrait is stamped upon the cover of the *Transactions of the Pathological Society of London*.

John Hunter was also a disciple of Bacon in that he employed induction in the pursuit of truth with an ulterior regard to utility and the good of mankind.

On the other hand, being a great thinker, he naturally inclined to the deductive method. But the tendency in

this direction was not so strong with him as with the purely deductive philosophers. He had not the deductive force of Descartes which could build up a profound philosophy with mathematical precision and by introspective examination, starting from a single subjective principle, such as "*Cogito, ergo sum*"—"Ego sum rex cogitans."

It was not as a logician, but as an observer and experimenter that Hunter excelled; it was not the beauty of his logic, but the industry with which he collected facts, and the ability and honesty with which he reasoned from them, which made Hunter great. He naturally possessed the special requirements for induction—namely, a desire for knowledge, the love of inquiry, acuteness of observation, ingenuity in devising experiments, and the habit of taking nothing for granted which he could verify for himself. Had it been otherwise, John Hunter might have become a deductive pathologist of the Scottish type, like the only other great British pathologist of the eighteenth century—the illustrious Scotsman, William Cullen.

If it be true, and I do not think it is, that in Hunter's mind the two philosophic methods were in rivalry or conflict, and that this conflict led occasionally to confusion of thought and obscurity of language, the perplexity arose from the very comprehensiveness of his mind, and the grandeur and vastness of its conceptions.

If, on the other hand, as I believe was the case, he employed at will both deduction and induction, but did not succeed in fully co-ordinating or completely combining the two methods, that was only because, notwithstanding his wonderful genius, he yet fell short of being an absolute monarch of the whole kingdom of the intellect.

An Address

ON THE IMPORTANCE OF EARLY DIAGNOSIS

IMPORTANCE OF EARLY DIAGNOSIS WITH A VIEW TO SUCCESSFUL TREATMENT.

DELIVERED BEFORE THE WESTMINSTER DIVISION OF THE
METROPOLITAN COUNTIES BRANCH OF THE
BRITISH MEDICAL ASSOCIATION,

BY A. W. MAYO ROBSON, D.Sc., F.R.C.S.

MR. PRESIDENT.—May I express the pleasure it has given me to be the guest of the Westminster Division of the British Medical Association, and the great honour I feel in being invited to open one of your clinical debates?

The proposition I wish to consider is, Are there not many cases seen by all of us (but especially by those who are acting as the regular medical advisers to their patients) in which the early symptoms, though definite and pronounced enough to enable a diagnosis to be made, are treated by palliative remedies simply for the relief of symptoms, and only at a later stage, when disabling conditions have developed or dangerous complications have ensued, is the importance of radical treatment insisted on? Some of these cases are such as could be easily cured by medical and general treatment carried out thoroughly, and with a set purpose, if the disease were recognized at its onset; in others, after medical treatment had failed to cure, surgical measures adopted at an early stage could be undertaken with hardly any risk, whereas if left until serious complications have supervened, operative treatment, then absolutely necessary, can possibly only be carried out with considerable danger to the patient and great anxiety to the relatives and to the professional attendants.

The blame for procrastination when a diagnosis has been made and absolute rest or rigid diet or other radical treatment advised must often be laid at the door of the patient or the friends, though we cannot always exonerate ourselves from tacitly sanctioning it; for as a rule our patients are prepared to place confidence in our knowledge and

judgement and to be guided by us if we are definite in our opinion, and especially if in consultation we are in agreement.

Much of the blame undoubtedly lies in a reliance on the traditions of the past, when means of making a diagnosis were less exact, when more faith was placed in treatment by drugs, and when operation yielded such results that the physician and the general medical attendant were very properly averse to invoke the aid of surgery, either for purposes of diagnosis or for radical treatment.

Let me might possibly run the risk of alarming our patients, I fear we are sometimes apt to reserve the many new means of diagnosis, such as an exhaustive pathological examination and examination by instruments of precision, to the later stages of illness, and not to place that reliance on them in the early conditions which daily experience shows they are worthy of being credited with—for instance, the early use of the sigmoidoscope where rectal examination by the fingers is negative, the employment of the x rays in obscure abdominal and thoracic conditions, a more thorough examination of the excreta and of the blood by a skilled pathologist, and many other means that involve the consent or even the co-operation of the patient.

It is quite unnecessary to dwell on the dangers of procrastination in the more obvious surgical conditions, such as strangulated bowel, perforative peritonitis and other similar catastrophes, where delay is well recognized to be dangerous, but I wish to draw attention specially to the disadvantages and dangers of procrastination, both in the diagnosis and in the treatment of that large class of diseases on the borderland of medicine and surgery, where a too prolonged medical treatment, quite capable of affording some relief, lulls the patient into a false sense of security.

DUODENAL ULCER.

Among this class let us first consider duodenal ulcer, now recognized to be a common ailment, often attended with the dangerous complications of hæmorrhage and perforation, both of which accidents demand surgical treatment under most unfavourable conditions.

I want to ask the question why we should wait for these serious catastrophes before making a diagnosis and radically treating the condition, seeing that the symptoms of duodenal ulcer (pain three to four hours after meals, relief by taking food or by taking alkalis, pain recurring regularly in the night or in the small hours of the morning, flatulency, tenderness over the duodenum, rigidity of the right rectus and frequently the presence of occult blood in the motions), are so characteristic as to enable an early diagnosis to be made with almost absolute precision. Moreover, the disease in the earlier stages is curable in a large percentage of cases by medical and dietetic treatment alone, whereas if left until numerous relapses have occurred or complications have supervened, it can only be treated radically, by operation.

As soon as it is seen that medical treatment has failed to cure, or failed to prevent relapses, why should we wait until hæmorrhage or perforation demands surgical treatment, when at an early stage the operation of gastro-enterostomy should prove curative with a modicum of risk—speaking not only from my own but from the experience of several other surgeons—of hardly over 1 per cent.?

CHOLELITHIASIS.

I would next draw attention to cholelithiasis, which until comparatively recent times was considered a painful malady, seldom or never attended by danger, the numerous serious and fatal complications to which gall stones give rise being apparently ignored.

In an experience approaching 1,000 operations on the biliary tracts, in many of which I have had to perform extremely difficult and dangerous operations on patients in the last stages of illness from deep jaundice, infective cholangitis, persistent vomiting, suppuration in the gall bladder, perforation of the bile ducts, or exhaustion from repeated attacks of pain, it has been more and more driven home to my mind how much better it would have been had operation been advised at an earlier stage, when surgical treatment would have been quite simple and the probability of recovery approaching 99 per cent., arguing not only from my own but from the experience of others, both at home and abroad.

Under ordinary circumstances, nothing can be simpler than an operation performed for gall stones on a normal-sized or slightly distended gall bladder, before the concretions have entered the common duct, and before the anatomy of the parts has become completely disarranged by adhesions and contractions, and before serious complications, both local and general, have manifested themselves.

Not least among the dangers, if concretions are allowed to remain, is that of malignant disease. It is well recognized that chronic irritation is one of the most potent causes of cancer, and the constant irritation of gall stones is in this respect a danger that cannot be ignored.

I have operated on many cases of cancer of the gall bladder and bile ducts and in a very large proportion have found gall stones. Zenker found gall stones present in 85 per cent. of cases of cancer of the gall bladder, Musser in 69 per cent., Courvoisier in 74 out of 84; Jale in 23 out of 30, Bertrand in 14 out of 15, Sievert in 95 per cent., and Brodowski in 100 per cent. of all cases examined. These facts cannot be ignored, and point so strongly to gall-stone irritation producing primary cancer of the gall bladder and liver that I think it ought to have weight with us in advising on the early diagnosis and surgical treatment of cholelithiasis.

Were the recognition of gall stones a difficult matter there would be much to say in favour of delay; but seeing that with comparatively few exceptions cholelithiasis may be recognized, even in the earliest stage (by the digestive symptoms with which it is associated, by attacks of discomfort in the epigastrium even before the characteristic symptoms are felt, by the irregular pain radiating round the right side to the shoulder blade, by the tenderness in the gall-bladder region, and by a careful pathological examination of the excreta, not for gall stones but for signs of disturbance in the upper bowel and the pancreas which are nearly always associated with early cholelithiasis), there can be little excuse for a failure to diagnose the condition. As soon as the later characteristic pains supervene, there is, of course, no need to wait for jaundice or the more serious manifestations in order to recognize the cause.

Here again medical treatment is capable of affording great relief. This it does not by causing dissolution of gall stones, but by relieving the catarrh and inflammatory conditions that are associated with them; but it does not remove the disease, and sooner or later patients who have been tided over the early manifestations develop complications of one kind or another that demand surgical treatment at a later stage and under much less favourable conditions. I have seen many such cases in which a diagnosis of gall stones had been made years before, but the relief of symptoms had put the patient in a fool's paradise, and only later, when serious complications had supervened or possibly cancer had developed, was the folly of delay made manifest. I proved many years ago—and an extended experience has further confirmed my observations—that the removal of gall stones can be undertaken at an early stage with hardly any risk, if the simple operation of cholecystotomy can be performed, but when the more formidable operations of choledochotomy, cholecystectomy, and other procedures have to be undertaken in the presence of jaundice, infective cholangitis or other serious conditions, the simplicity and safety of operation can no longer be urged.

CARCINOMA OF THE STOMACH.

This is one of the diseases which, if caught in an early stage, can be cured in a considerable proportion of cases. Unfortunately it is difficult of diagnosis in an early condition. No one has done more than Professor Osler to advocate an early diagnosis of cancer of the stomach, if needful by an exploratory operation, in order that radical treatment may be carried out at a time when there is a hope of cure; and if only this truth could be impressed on those who see these cases in an early condition, at a time when the symptoms are merely those of dyspepsia, and if, in such doubtful cases, a consultation were insisted on, so that the matter might be taken seriously at the earliest possible moment, we should find that much could be done for these otherwise hopeless cases.

When so little was possible from either medical or surgical treatment, the early diagnosis was of little moment.

from a practical point of view, but now that surgery has proved it possible to remove cancer of the stomach, when seen early, before a tumour or other pathognomonic symptoms have developed, the importance of an early diagnosis cannot be too strongly insisted on. There is ample evidence to show that for some length of time cancer is purely a local disease, and just as in the breast, the tongue, and the uterus we can point to patients living comfortable and happy lives many years after the removal of the disease, so in gastric cancer it is reasonable to estimate, and, in fact, can now be proved by positive evidence, that a like result may be anticipated.

Whenever a patient at or after middle age complains somewhat suddenly of indefinite gastric uneasiness, pain, and possibly vomiting, followed by loss of weight and energy, especially if associated with anaemia, the possibility of cancer of the stomach ought to be entertained, and if no improvement takes place in a few weeks at the most, an exploratory operation is more than justified, and ought to be more frequently advised and carried out. Although a chemical examination of the stomach contents and a general examination of the patient may give strong grounds for suspicion, our diagnosis can often only be rendered certain by a digital examination, which may be effected through a small incision, that can, if needful, be made under local anaesthesia, and that without more risk, if in an early stage, than ordinarily attends the administration of an anaesthetic. I can point to patients living and well from whom I removed cancer of the stomach so long as eight or more years ago, and many other surgeons can give similar experiences.

Even at a later stage, supposing a diagnosis has not been made until a tumour has developed, operation is worth performing, as relief can be given and life prolonged by the operation of gastro-enterostomy. I am, moreover, firmly convinced that many deaths are ascribed to cancer when the disease is inflammatory, and perfectly curable by gastro-enterostomy without removal of the tumour; and did time permit of it I could relate a number of instances in which I have done this operation, because I thought the tumour of the stomach, which I believed to be cancer, was too large and too extensive to remove, in which the patients have made a complete and permanent recovery and are perfectly well now, years after operation.

Although there is no pathognomonic symptom of early cancer, the absence of free HCl in the gastric contents after a test meal is suspicious, as is also the presence of albumose in the urine, of blood in the faeces, and of Salomon's test—the finding of a certain amount of albumen in the stomach contents some hours after it has been thoroughly cleared by lavage.

SIMPLE ULCER OF THE STOMACH.

This is another disease I would specially mention, as if diagnosed early and treated radically at first it is quite curable by medical treatment in a considerable proportion of cases, whereas if merely treated palliatively the disease is almost certain to relapse and to become chronic.

Only last week I operated on a lady who had suffered from stomach symptoms continuously for twenty years, during which time she had had every imaginable form of treatment. At the operation I found, as suspected, a large chronic ulcer along the lesser curvature of the stomach, which had led to a marked hour-glass contraction. This is a good example of many similar cases that I have seen, in which the patients, after suffering and being treated year after year for symptoms, which no amount of medical treatment could possibly cure, have had at last to submit to operation or to lose their lives. Had the disease in this case been diagnosed in an early condition and thoroughly treated by diet and rest, she might have been saved these twenty years of suffering.

Leube has shown that at least one-half to three-quarters of all cases of ulcer will be cured by early medical treatment, but if they are not cured in that time they will not be cured by medical treatment alone.

The more recent observations made at the London Temperance Hospital by Mr. Paterson and Dr. Rhodes on 153 consecutive cases, under the care of Dr. Soltan Fenwick and Dr. Parkinson, are still more striking, showing that the proportion of real cures in cases of confirmed chronic ulcer, even after prolonged treatment by diet and rest in hospital, is under 25 per cent. I have elsewhere

given my views on this subject, and shown how safe and successful surgical treatment is—the risk, for instance, of gastro-enterostomy being very little over 1 per cent. But what I plead for now is an earlier recognition of the condition, so that adequate medical treatment may be applied in time, in order to save the necessity of having to appeal to surgery.

The symptoms of gastric ulcer are so well known as to need no further description now, and the serious complications of perforation, haemorrhage, hour-glass contraction, cicatricial stenosis, gastric dilatation, extensive perigastritis, perigastric abscess, inflammatory tumours, fistula, and others that could be mentioned, only go to prove how serious for the patient the want of early diagnosis and of radical treatment have been. Moreover, it is now clearly and definitely proved that chronic irritation due to long-continued ulcer is an undoubted cause of cancer, which complication might be prevented by an early diagnosis and treatment.

My conclusions are not the vain thoughts of mere imagination, but have come as the result of an experience approaching 1,000 operations of one kind or another on the stomach.

OVARIAN TUMOUR.

To pass to an entirely different subject. I have operated some hundreds of times for large ovarian tumours, and many times with serious complications. The question has often crossed my mind during the operation, Why should these cases have been allowed to go on so long before being submitted to operation, when no amount of medical treatment could have done an atom of good, and they could have been recognized in their infancy by a bimanual examination, and removed with almost absolute certainty of recovery before any complications had supervened? Here an early diagnosis and early treatment would have saved the danger of suppurating cyst, twist of the pedicle, ruptured cyst with general peritonitis, and many other complications that are apt to supervene at all stages of this disease.

CANCER OF THE UTERUS.

So much has been written recently on the importance of the early diagnosis and treatment of cancer of the uterus by an examination of all cases of irregular intermenstrual bleeding or post-climacteric haemorrhage that the subject need not be further dwelt on; nor is it necessary to labour the question of a careful examination of the rectum, if needful by the sigmoidoscope, in cases of rectal discomfort or haemorrhage in middle or advanced life in order to recognize and treat cancer in that region at the earliest possible moment.

DIAGNOSIS OF THE CAUSE OF JAUNDICE.

Although I should have liked to insist on the importance of an early diagnosis in appendix trouble and the desirability of absolute rest, of absolute starvation, and of the avoidance of the routine aperient in all cases of abdominal colic until a diagnosis of the cause has been established, by which many operations in the acute and dangerous stages might be avoided, and although I should have liked to dwell on the early diagnosis of cancer in various positions in order that a timely radical operation might be done, I must omit them for want of time, and I will only give one more example, and that is the symptom of jaundice and the early diagnosis of the cause with a view to successful treatment.

The onset of jaundice after 35 to 40 years of age is an important event that may herald a condition which will slowly yield to general treatment, which may demand operative treatment for its cure, or which may prove to be incurable. To treat such cases simply as catarrhal jaundice after medical treatment has been pursued for two or three weeks without relief, is to my mind unjustifiable procrastination.

Careful clinical and pathological investigation is therefore, from my point of view, incumbent on the medical attendant at a much earlier stage than is often considered necessary, as on the diagnosis will depend the treatment.

As I have recently given my views on the subject at one length before the North London Medico-Chirurgical

Society in a paper which has been accepted for publication, I need not enter at length into the various causes.

Gall stones in the common duct should be readily diagnosed, with few exceptions, by the previous history and by the attacks of pain, followed by an increase of jaundice, frequently associated with symptoms of infective cholangitis, and, as soon as diagnosed, I think they ought to be removed by cholecystotomy before more serious complications supervene.

Jaundice of painless origin is seldom due to cholelithiasis, but, if due to interstitial pancreatitis, it may be diagnosed by a careful examination of the excreta, and by the discovery of the pancreatic reaction in the urine and the presence of urobilin, and by the discovery of an excess of neutral fat in the motions, and the evidence of an incomplete obstruction of the common duct as shown by the presence of stercoribilia in the faeces. In many such cases, medical and general treatment, thoroughly carried out, will bring about relief or cure; but if the obstruction is persisting after a month, or at most six weeks, of treatment, the question of exploratory operation ought to be considered with a view to removing the cause, if that be possible, or of short-circuiting the obstruction where the cause cannot be taken away, for it is to be borne in mind that the circulation of bile in the blood tends to its deterioration, and to the production of a haemorrhagic tendency, which makes later operations more dangerous, whereas an early operation can be done with very little risk and a probability of recovery in 97 or 98 per cent. of cases.

If the clinical and pathological examinations give rise to a strong suspicion of cancer of the pancreas or of the common bile duct I would still advise exploration before the more advanced blood changes and changes in the liver owing to biliary congestion render even an exploratory procedure a matter of some anxiety and danger; moreover, it is a fact that a short-circuiting of the gall bladder into the duodenum has been followed by cure in quite a number of cases in which both my medical friends and I thought the disease to be undoubtedly malignant; but in any case, even if really malignant, relief to the distressing symptoms of jaundice may be given by a cholecyst-enterostomy and will be gratefully appreciated by the patient.

Were it necessary further to illustrate my proposition, it would be easy to give further examples of diseases in which an early diagnosis is of vital importance to successful treatment both medical and surgical, but where the mere treating of symptoms and a delay in making an exact diagnosis necessarily postpones rational treatment until the disease may be too advanced to yield to general and medical measures or possibly even too serious for relief by surgical treatment except at a greatly increased risk.

It was announced in the JOURNAL of January 23rd that an anonymous benefactor had given £20,000 to the London Hospital Medical School, with the express stipulation that the interest accruing therefrom should be applied solely in furtherance of medical research. We learn from the *London Hospital Gazette* that the fund has been placed in the hands of the London Hospital Medical College Endowment Fund, Mr. Douro Hoare, the Hon. H. L. W. Lawson and Sir Frederick Treves, whilst the administrators are the Honourable Sydney Holland, Dr. Bertrand Dawson, and Dr. Henry Head. Although the administrators will be responsible for the manner in which the income of the fund is to be disbursed, they will invite the heads of departments to express their views, and will be ready to consider the claims and suggestions of individuals. The donation will form the nucleus of an endowment fund which, according to the scheme set forth in the prospectus, will be applied for the following purposes: (1) To secure the maintenance of the London Hospital Medical College in full efficiency and equipment, so far as buildings, laboratories, and apparatus are concerned, for the investigation of disease and its treatment, with a view to the lessening of human suffering; (2) to secure for the college the services of teachers and investigators of the highest standard; (3) to improve medical education generally; (4) the liberation of the college from its existing debt, which has been contracted in attempting to carry out these objects. The sum required for these purposes will be at least £150,000.

The Morison Lectures

PATHOLOGY OF SYPHILIS OF THE NERVOUS SYSTEM IN THE LIGHT OF MODERN RESEARCH.

[With Special Plate.]

DELIVERED AT THE ROYAL COLLEGE OF PHYSICIANS, EDINBURGH, JAN. 25TH, 27TH, AND 29TH, 1909.

BY F. W. MOTT, M.D., F.R.S., F.R.C.P.

DIRECTOR OF THE PATHOLOGICAL LABORATORY, LONDON COUNTY ASYLUM; PHYSICIAN TO CHARING CROSS HOSPITAL.

LECTURE I.

MR. PRESIDENT AND FELLOWS OF THE COLLEGE.—Allow me to thank you for the great honour of having been invited to give the Morison Lectures in this ancient College of a city so long renowned as a great seat of medical science and learning.

In considering the general pathology of syphilis of the nervous system, it is not necessary to refer to the different bacterial and other organisms which have been described by various authorities as being the specific agent in the production of the lesions characteristic of this disease before the discovery of the *Spirochaeta pallida* by Schaudinn. This organism, whether it be, as its discoverer believed, a protozoon or a bacterium or micro-organism between a protozoon and a bacterium, is regarded as the specific organism of syphilis by these best competent to judge—namely, Metchnikoff, Hoffmann, Neisser, Levaditi, Bertarelli, Shennan, and many others. Metchnikoff and Roux were the first to demonstrate experimentally the communicability of syphilis to animals, and to show that the nearer the animal approached to man the more the disease approached in its characters and virulence the human form of the malady. Thus, although other animals, especially apes and anthropoid apes, have been successfully inoculated, the chimpanzee alone reproduces with absolute certainty the human symptomatology. This is as we should expect, for the blood precipitin reaction of this anthropoid approaches most nearly that of man. The experiments of Neisser, Hoffmann, Bertarelli, Levaditi, and numbers of others have confirmed this important discovery, and many new facts have been added to our knowledge of the general pathology of syphilis by experiments on apes and other animals, and I would mention in particular the important discovery by Bertarelli that he was able to inoculate the spirochaete into the cornea of the rabbit and transmit it through a series of such animals. Levaditi has experimented successfully with the cornea from one of these animals, and not only transmitted it through a series of rabbits, but used the cornea infected with spirochaetes to produce an infection of the eyelid of an anthropoid ape. Lastly may be mentioned the important observations upon the bio-chemical changes in the fluids of the body by the Wassermann-Neisser-Brück method of serum diagnosis. Upon this tripod, of the discovery of the specific spirochaete, the communication of the disease to apes, and the serum diagnosis, a vast amount of most valuable work rests; the tripod is mutually supporting, and every day fresh evidence is forthcoming to strengthen the opinion that the true cause of syphilis has been discovered; that, although as yet no vaccine has been successful, this is no longer a hopeless outlook; and, lastly, a most valuable means of diagnosis of syphilis and parasymphylis has been obtained.

THE MICROBIOLOGY OF SYPHILIS.

The *Spirochaeta pallida* examined in fresh preparations is seen with much greater difficulty than other coarser spirochaetes which may exist in the primary sores on the genitals or secondary papules of mucous surfaces. Hoffmann states, in order to find them, seek the edges of red blood corpuscles, to which they often are seen to be attached by one end (a process of climitropism). It is barely $\frac{1}{2}$ μ thick, and possesses on an average 8 to 12 very regular, narrow, and very steep coils, the height of which at the ends diminishes somewhat (vide Figs. 1, 2, 3, 4 in Plate). The length of this corkscrew-like organism varies within wide limits, from a few up to

26 coils or even more. Examined with a paraboloidal reflecting substage condenser, by which living organisms appear light on a dark background, the *Spirochaeta pallida* can be seen to rotate on its long axis and oscillate to and fro with a pendulum-like movement, contrasting thus with the coarser and larger spirochaetes, which have an eel-like movement. An observation of Hoffmann showed that the untreated serum of a syphilitic patient caused a cessation of movement after about a couple of hours.

(Hoffmann.)

DIFFERENCE BETWEEN THE *SEREBRIS-SPIROCHAETE* AND OTHER KINDS OF SPIROCHAETE. — (Hoffmann.)

Spirochaete.

Other Forms.

1. Large size, 10 to 15 μ on the average, still often more than this. The extreme tenuity of the fibre itself. This relation between length of fibre and its thickness is very characteristic.
2. Very slightly refractile in fresh preparations, therefore only visible with the best apochromatic lenses.
3. Ends are pointed, often terminating in long red threads.
4. Movements screw-like around their long axis; lateral pendulum movements; movements forwards and backwards still less active, often remains a long time inactive anchored to a blood corpuscle whilst it exhibits rotatory and slight geniculum movements.
5. The spiral possesses deep, steep, and very regular coils of corkscrew form. Fibre excessively thin in comparison to the length and depth of the spiral.
6. Relation of the depth to the length of the coils mostly greater than 1—namely, 1.0-1.2; 1.0-1.5.
7. Great elasticity and retention of the spiral form, therefore with more difficulty deformable.
8. Only trifling variations in breadth in respect to the form; only the length, therefore also the number of coils, variable.
9. It is coloured by Giemsa, red (general scattered chromidial substance).
1. Fibres relation to their length far thicker, therefore they have a plumper appearance; the finer forms are mostly shorter than the *Spirochaete pallida*.
2. Strongly refractile, and therefore easily seen in fresh preparations.
3. Ends blunt. End threads seldom seen.
4. Lateral movement much more active, eel-like and sinuous, and more rapid change of position. Anchors to cells much less frequently, and detaches itself quicker.
5. Coils flatter, irregular, in many forms (*Sp. dentium*) narrower fibres, thick and plump in comparison to the breadth of the coils.
6. The known relation is smaller than 1.
7. Softer and more pliable, therefore the form is more changeable.
8. Greater variability, all transitions from small to large, from thick to thin examples.
9. Colour more bluish-red; nuclear rod or rod-nucleus in plasma often demonstrable.

Schaudinn and Hoffmann were able to prove that the *Spirochaete pallida* is found in all cases of syphilis, and is never found in any other affections. They also discovered spirochaetes in fresh preparations, not only on the surface of the chancres and papules, whether of the skin or mucous membranes, but also in the depths of the tissues and in the juice of enlarged inguinal glands of syphilitic cases. Metchnikoff, Roux, and Levaditi have demonstrated the presence of the spirochaetes in chancres on the face and penis of monkeys in association with other organisms; they also found the spirochaete in papules. Buschke and Fischer discovered spirochaetes in abundance in the liver and spleen of an infant affected with congenital syphilis, and Levaditi demonstrated numbers of spirochaetes in the fluid contained in the bullae of pemphigus occurring in a congenital syphilitic infant. Since then an ever-increasing army of workers have, with a few notable exceptions (Saling, Schulze), supported the discovery of Schaudinn. In fact, this organism has been shown in every possible lesion which is definitely syphilitic (Metchnikoff). In some cases they cannot be found in the primary sore unless a very careful search is made, and even then the search may not be successful. The same applies, with even more force, to the secondary eruptions.

The spirochaetes have been discovered in the capillaries of the skin and in the perivascular tissue. Although only occasionally found in the blood, the spirochaetes are more numerous in the lymph and lymphatic organs in general, and, according to Metchnikoff, their presence in lymphatic

vessels may be said to be constant in syphilis, and it is at times possible to see a very large number in the perivascular spaces although their number in the corresponding blood vessels may be exceedingly limited. I have examined a number of primary sores, mucous tubercles, and cutaneous papules sent to me from the lock hospital, also fetal tissues and the tissues of several congenital syphilitic infants, and in all cases smears have shown spirochaetes by the Giemsa method, sometimes, however, only after long and diligent research. In one case of secondary papules I found the spirochaetes by the Levaditi method, although I was unable to find them in the blood. When the disease becomes generalized and there is a polyadenitis, the organism can be found in glands far removed from the primary lesions; thus Lewandowsky found spirochaetes in the juice of the epitrochlear gland. It is presumed that for a short time, perhaps some hours, the organisms remain in the lymph clefts and spaces of the tissues at the point of inoculation; there it multiplies, and in a short time extends into the lymphatics and produces microscopic changes; although macroscopic changes are not visible. In confirmation of this it may be mentioned that Levaditi and Yamanouchi have inoculated the chimpanzee with syphilis, and at a time when the point inoculated did not show the slightest microscopic indication of primary syphiloma they were able to detect an active pullulation of spirochaetes and specific histological changes. The same investigators have recently published some very interesting researches upon incubation in syphilis. These observers, by a series of observations on keratitis in the rabbit induced by introducing a small portion of an infected cornea into the anterior chamber and by killing the animals at varying periods of time afterwards, also by introducing the infected cornea of the rabbit beneath the skin of the eyelid in apes and a chimpanzee eyelid and examination of the tissues for spirochaetes by the Levaditi method, formulate the following conclusions: The period of incubation which precedes the manifestation of the primary syphiloma of the monkey and the specific keratitis of the rabbit is not due to the existence of an evolutionary cycle of the *Treponema pallidum*. It corresponds to the slow but progressive histological lesions provoked by the pullulation of the microbe of syphilis. This pullulation is not marked at first, in consequence of a defective assimilation, caused on the one hand by a change of medium, and on the other, by the conditions which preside over the supply of nutritive materials. But, as soon as the vessels and new-formed cellular elements assue to the treponema the nutritive principles of which it has need, the multiplication by the parasite becomes active, and puts an end to the period of incubation.

The organisms after local development at the point of inoculation in man and in the anthropoid ape soon reach the nearest lymphatic glands, where probably they again multiply in the lymph sinuses and spaces, setting up an adenitis; these changes may be biological, provoked by the organism for its perpetuation, and not altogether in the nature of a defence on the part of the tissues against the invasion by the organism. The living organism usually prevails and passes into the general lymph stream, causing polyadenitis and an infection of glands remote from the seat of inoculation. The organisms may thus find their way into the thoracic duct, and a general infection of the blood stream takes place, with the development of the secondary eruption (rosola). Moreover, a profound bio-chemical change occurs in the blood and fluids of the body. Occasionally, as first pointed out by Lang, and as I myself have observed in several cases, quite early in the disease, even before the primary sore is healed, symptoms pointing to meningitis may occur; also, as will be pointed out later, and which I have seen illustrated by many examples, the most severe and the most intractable cases of brain and spinal syphilis occur within the first twelve months after infection; it is quite probable that the meninges were infected at the time of the rosolar rash in some of these cases, but the symptoms occurring then were slight and overlooked. Not infrequently severe symptoms of meningitis have occurred within a few months of the primary sore. I have had one case in which well-marked signs of meningitis occurred while the sore was yet unhealed. It is reasonable

* Some authors prefer this term to *Spirochaete pallida*.

to suppose that if the spirochaete is the cause of the secondary cutaneous eruption by a sort of metastatic process in the skin capillaries, the same may occur in the meninges. The following case reported by Gautier and Maloizel is interesting in this respect, and tends to support that conclusion: A young woman affected with secondary syphilis had seven successive attacks of cutaneous eruption, simultaneously with sudden fever, headache, stiffness of the neck, and vomiting, accompanied by lymphocytosis of the cerebro-spinal fluid—a complex of symptoms of syphilitic meningitis. Again, Boidin and Weil have reported a most interesting case of a young man, aged 18, who had (1) a hard chancre in the middle of June; (2) headache in the middle of July; symptoms of meningitis and lymphocytosis of cerebro-spinal fluid August 5th; roseolar rash August 12th. Cure of the meningitis by injection August 17th.

It is a pity that some of the fluid of such cases was not used for experimental inoculation on an ape. So far only Hoffmann has succeeded in showing that the cerebro-spinal fluid may be infective, for he has successfully inoculated a monkey with the cerebro-spinal fluid obtained blood free, and taken with all precautions from a man suffering with a papular syphilide. Neisser states that Dohio and Tanaka have found spirochaetes in the cerebro-spinal fluid in the case of a patient with a papular eruption; a second examination, as well as one by Neisser himself, was unsuccessful. It may be that centrifuging a fluid of such low density would disintegrate such delicate organisms. Again, we know that it is not infrequently impossible, except by culture or inoculation, to find tubercle bacilli in the cerebro-spinal fluid of tuberculous meningitis. Until experimental investigations have been made with fluid obtained from early acute cases of syphilitic meningitis, the absence of the organisms upon microscopic examination, and failure of experimental inoculation is no valid argument against their being the cause of the meningitis. It may be said that if the spirochaetes are the cause of the meningitis, they could be shown in sections or in films of the exudation. It is seldom that syphilitic meningitis is rapidly fatal, and cases would rarely come under early enough observation; moreover, not more than 1 or 2 per cent. of syphilized persons suffer with obtrusive symptoms of meningitis, and they seldom die in consequence thereof, and still more rarely do they die for at least some months after the onset of symptoms. I have been unable by the silver or Giemsa method to find spirochaetes in the exudation of typical cases of syphilitic meningitis. But I was unable to find trypanosomes in the similar cell infiltrations of the meninges and perivascular spaces of sleeping sickness, although I have examined quite a thousand sections obtained from 30 cases. Yet, it cannot be doubted that the *Trypanosoma gambiense* is the exciting cause of the meningo-encephalitis.

Syphilis is characterized by being an eruptive malady following the inoculation of the virus, presumably the spirochaete of Schaudinn, and by the possibility during the remainder of the life of the individual of fresh eruptions occurring in connexion with the existence of the virus in the body. A blow may be followed by a gumma, or a syphiloma may occur spontaneously in any part of the body at any period of time after infection. Microscopic examination shows that essentially the same tissue reactions occur in these late manifestations of syphilis as in the primary or secondary stages. It is well known that tertiary

lesions are, as a rule, non-infective; consequently we should not expect to find the active agent, or what we believe to be the active agent—*Spirochaeta pallida*—except in a few instances, and then only in small numbers. This is actually what has occurred. For a long time attempts to prove the existence of the spirochaetes in tertiary lesions failed, and this led to the not unwarrantable view (which may be true) that the organism may exist in a latent and attenuated, possibly intracellular, form, and it is possible that late manifestations may be the result in some cases of secondary lesions which have remained latent until raised into activity by some exciting factor, such as exposure to cold, trauma, and toxæmia—microbial or otherwise. For at no period after infection may not such syphilitic meningitis occur. I have described a case of congenital syphilis in which cerebro-spinal meningitis occurred in a girl of 16. I was unable, however, to find spirochaetes, although the meningitis was very active and typically syphilitic in its histological character. It must be admitted that this is a part of the microbiology which is unsatisfactory. The spirochaete, however, has, in a few instances, been found in a gummatous tumour. Schandinn found it in a gumma of the liver. Blaschko recently claims to have discovered spirochaetes in scrotal papules which occurred sixteen years after infection. Reuter and Schmorl claim to have found

spirochaetes in syphilitic aortitis embedded in the proliferated intima between the fibrils, sometimes in places in which regressive changes are absent. Moreover, Benda claims to have demonstrated typical spiral, straight, and granular forms of the spirochaetes in the external layer of the media, and still more in the connective tissue adjacent to a patch of syphilitic endarteritis. Just as there are, relatively, but few successful observations proving the existence of spirochaetes in tertiary lesions, so there are, relatively, few successful experiments of inoculation of animals from tertiary lesions. Hoffmann has, however, succeeded in inoculating an ape from a gumma occurring in a man three and a half years after primary infection.

It has already been stated that the *Spirochaeta pallida* is an organism between a bacterium and a protozoan, and in spite of the divergent views respecting the classification of spirochaetes, there are, in my judgement, more characters linking them to the protozoan than to the bacterium. The *Spirochaeta pallida* contracts, moves, and modifies its structure in a manner different to a bacterium. The appearance of resting forms is totally different, and they arise in a different manner to the spores of bacteria (Prowaczek). Again, the clinical aspect of affection from spirochaete invasion differs from that of bacterial diseases, and conforms especially to certain trypanosome infections. There is a periodicity of the symptoms altogether unknown in bacterial diseases. But, what has struck me from my own personal experience and knowledge, is the great similarity of the histological lesions of the nervous tissues of chronic trypanosome infections—for example, sleeping sickness and dourine—to syphilitic and parasymphilitic lesions (vide Plate). The universal perivascular infiltration in the central nervous system of lymphocytes and plasma cells was thought by Nissl and Alzheimer to be pathognomonic of general paralysis and syphilis, but I have shown that exactly the same occurs in sleeping sickness. In the *mal de coit* of horses an ataxic paraplegia occurs, and I have found, in five specimens sent to me by Dr. Lingard from the Imperial Bacteriological Institute of India, posterior root degeneration and

DESCRIPTION OF FIGURES ON PLATE.

Fig. 1.—*Spirochaeta pallida*, smear preparation of condylocoma, stained by Giemsa solution. Magnification, 3,400.

Fig. 2.—Another portion of the smear, showing appearances of two spirochaetes twisted around one another; possibly this is the result of longitudinal fission. Magnification, 3,400.

Fig. 3.—*Spirochaeta pallida* from smear preparation of mucous tubercle. Magnification, 1,800.

Fig. 4.—Section of spleen from a case of congenital syphilis, stained by the Levaditi method. Magnification, 1,400.

Fig. 5.—Perivascular infiltration with lymphocytes and plasma cells, stained with polychrome blue, from a case of gummatous cerebro-spinal meningitis. Magnification, 250.

Fig. 6.—Section of central nervous system from a case of sleeping sickness in a European, showing perivascular infiltration with lymphocytes and plasma cells. Magnification, 250.

Fig. 7.—Section of a small vessel showing the sheath infiltrated with lymphocytes and plasma cells and with proliferated glia cells. Experimental sleeping sickness in an ape. Magnification, 320.

Fig. 8.—Section of cortex cerebri from a case of sleeping sickness in a European, stained to show the neuroglia. Magnification, 450.

Fig. 9.—Section of brain of ape infected with *Trypanosoma gambiense*, showing perivascular neuroglia cell hyperplasia. Magnification, 320.

Fig. 10.—Blood smear from a case of sleeping sickness, showing *Trypanosoma gambiense*. Magnification, 2,000.

Fig. 11.—Blood film showing *Trypanosoma brucei*. Magnification, 1,700. It will be observed that it would be difficult to decide the nature of the parasitic organism by morphological characters alone.

All the figures, with the exception of 7 and 8, are photomicrographs; these two figures are from drawings made by Dr. Edgar Schuster.

sclerosis of the posterior columns of the spinal cord. Spielmeyer has obtained by experimental trypanosome infection of dogs a lesion of the posterior columns of the spinal cord simulating the ataxic lesion; he has also produced optic atrophy. Again, there is similarity in the fact that lymphocytes and plasma cells are found in the cerebro-spinal fluid in trypanosome diseases of animals and man—for example, sleeping sickness. Moreover, Levaditi has shown that, in point of view of sensibility in respect to haemolyzing poisons, blood corpuscles, spirochaetes and protozoa constitute a homogeneous group, and the spirochaetes correspond in this respect more to the protozoa than the bacteria.

The study of all these diseases is primarily biological. The contagium vivum is a living organism whose activities, like that of all living organisms, are for self-preservation and the preservation of the species. The chemical toxin which the organism produces is to enable it to live and multiply. The spirochaetes consist of a viscid plasma covered with a membrane which serves as a means of osmosis. This osmotic membrane is a lipid substance, like that which forms the membrane of the red corpuscles, and is sensitive to haemolyzing substances.

The fact that Castellani has discovered a spirochaete, which he terms *Spirochaeta pallidula*, in yaws is of importance in showing that a spirillary organism not quite morphologically identical with that of syphilis is probably capable of producing a chronic disease in many of its features not unlike syphilis. It might be argued that all the postulates laid down by Koch have not been fulfilled, and, therefore, that we have no right to claim that the *Spirochaeta pallida* is the specific organism of syphilis. Thus the organism, although it has been grown in celloidin capsules, has not been cultivated on an artificial medium outside the body, and the disease reproduced by injection of such a culture. But the same argument might be applied to certain established protozoal diseases—for example, malaria and sleeping sickness.

Dourine may almost be regarded as the syphilis of equines, for it is characterized by an infective sore on the genital organs, affection of the nearest lymphatic glands, then infection of the blood stream followed by successive eruption of plaques; and, as in syphilis, so in dourine and sleeping sickness, the juice of the lymphatic glands, in a condition of acute swelling, shows the specific organisms more readily than the blood films. The trypanosomes may disappear from the blood entirely, even without the administration of drugs, and reappear, giving rise to an irritating eruption of papules and fever, and the trypanosomes can be found in smears obtained by scarifying the papules more readily than from smears of the blood. This was demonstrated by Lingard in the case of *mal de coit* of horses, and by the French observers in a case of sleeping sickness. So, also, in syphilis I have been able to find an abundance of spirochaetes in the secondary papules of the skin, although I was unable to find them in the same cases in the blood films. It is a remarkable fact that Neisser was unable to inoculate animals by injecting the virus into the blood or into the organs; success was only obtained by scarifying an epiblastic skin surface and rubbing in the virus. This is precisely the seat of eruptions and pullulation. It looks as if the organism, to perpetuate the species, must find its way out of the body in the way it came in. Sir Patrick Manson (Huxley Lecture) expressed the opinion that, by analogy, we must presume that all trypanosome diseases are carried by some biting insect which acts as alternate host. But dourine spreads in the same way as syphilis. It is quite possible that the *Trypanosoma equiperdum*, which differs very little from the *Trypanosoma evansi*, may be this trypanosome which has acquired the habit of pullulation in the mucous cutaneous orifices, and, when infection occurs, always tends to get back there. In syphilis the same habit may have been acquired. It is known that mucous tubercles and condylomata (secondary eruptions) are more infective than the primary sore, and contain immense numbers of spirochaetes. Similarly, upon reading Lingard's experiments, I find he mentions that the *Trypanosoma equiperdum* was found in great abundance sometimes in the vaginal mucus when it could not be found in the blood. Again, he was more successful when he inoculated animals by scarifying the genitals and

inoculating with blood from a papule or with vaginal mucus than when he injected the blood into animals. These facts accord very much with Neisser's experiments, and would seem to indicate that a habit had been acquired by the *Trypanosoma equiperdum* of developing in the mucous membrane of the genital organs, and of using this acquired habit as the means of preserving the species.

Finally, the therapeutic agents, mercury and arsenic in the many forms employed, are specific for both trypanosome and spirochaete affections. They are not of much use for bacterial infections. Mercury, particularly in the form of inunction, is especially valuable; and this may be owing to the fact that it prevents the pullulation of the spirochaetes on the surface of the body, including the mucous orifices, a habitat which these organisms have found particularly favourable for perpetuation of the species by transmission to another individual. Mercury, moreover, administered in any way, tends to come out by the skin, as can be readily demonstrated.

I have pointed out that, practically, the morbid tissue changes in syphilis are similar, whether the lesion be the primary sore or a gumma twenty years later; moreover, it is difficult to understand how the spirochaete, seeing that it has hardly ever been found in tertiary lesions, can produce the same specific cell hyperplasia so long after the primary infection. The following hypotheses may be put forward to explain the phenomenon of a gumma appearing spontaneously in the central nervous system long after the primary sore and apparent cure of the disease:

1. The spirochaete, or some modified form of it, has remained latent in the tissues at the seat of the lesion, and, for some reason, inherent or otherwise, the resistance of the tissues at that particular spot has become lowered, and the organism has exerted again its specific activity—possibly in some not yet discovered intracellular form.

2. The specific organism has remained latent in some other tissue—for example, the marrow of bone, the spleen or glands—and, escaping into the blood or lymph circulation, has, like a new growth, engendered a metastasis, which has developed and increased, producing a hyperplasia of the fixed tissue cell elements, conjunctival and endothelial.

3. There may be varieties of specific spirochaetes, one of which may have an elective affinity for the central nervous system, as we know the *Trypanosoma gambiense* has. It is difficult to differentiate this trypanosome from other forms by morphological appearances (vide Fig. in Plate); how much more difficult would it be to differentiate varieties of *Spirochaeta pallida*!

4. The invasion of the body by the spirochaetes has altered the blood and lymph bio-chemically, so that the tissue reactions to all causes which would lead to injury may take on the specific character.

Thus a blow on the head, vascular stasis, or some inherent weak spot may become the seat of a gummatous process. Although we are only beginning to unravel these biological problems, the evidence so far appears to be in favour of the fixed tissue cell hyperplasia with subsequent necrobiosis being a reaction to the influence of the specific organism. The fibrosis may be regarded as the attempt on the part of the tissues to repair the damage done in the struggle between the specific virus and the tissues; it is accomplished by the young connective tissue cells which have survived the fray; these are converted into fibroblasts and eventually into sclerous fibrous tissue. The amorphous caseous material is the residuum of the dead cells and organisms, especially the former, which, owing to the toxic influence of the virus and the cutting off of the vascular supply, have undergone necrolysis and plasmolysis. The organisms, when found, are not discovered here when the struggle is past, but at the growing edge, where the new blood vessels and embryonic cell hyperplasia is most active; for it is here that the organism finds pabulum for its multiplication.

LECTURE II.

In my last lecture I endeavoured to point out some facts and hypotheses of the biological problems of syphilis, especially in relation to disease of the nervous system. To-day I wish to draw your attention to modern researches bearing upon the bio-chemical changes which occur in the tissues and fluids of the body as a result of the entry and persistence of the syphilitic virus in the body.

I must, however, first make a slight digression, in order that you may obtain a better understanding of the altered bio-chemical conditions; this digression refers to the nature of lipoids—substances which have recently, in connexion with haemolysis, attracted a great deal of attention, and I wish here to acknowledge my indebtedness to Dr. Rosenheim for valuable information. "There seems to be a good deal of truth in the opinion of Bang that the importance of proteins as carriers of life (*Träger des Lebens*) has been over-estimated, while that of the lipoids has been neglected." Pfüger and most physiologists have taught that the vital activities depended essentially upon proteins. Bang contested this exclusive view. The name "lipoid" was given by Overton to fat-like substances which are contained in the cells of all living things, animal and vegetable. They were named by Waldemar Koch "lecithans," but this name has not been adopted. These lipoids may be divided into three groups: (1) N and P-free cholesterolin, fatty acids, and lipochromes; (2) nitrogenous but P-free cerobrosides; (3) phosphatides containing both N and P. Of these, the most important are the mono-amino phosphatide *lecithin* and the di-amino-phosphatide *sphingo-myelein*.

These lipoids were, until recently, considered of little importance; in fact, cholesterolin was looked upon as a physiological curiosity by virtue of the fact that its crystals had a chip out of one corner, and little else was said about it except that it was contained in the red blood corpuscles and formed the principal constituent of gall stones. Lecithin was known to be a constituent of the red corpuscles, but it was not until Flexner and Noguchi's experiments on cobra venom had been published that the importance of these bodies in the action of toxins aroused attention. They found that cobra venom contains two poisons, a neurotoxin and a globulin which has the property of dissolving red corpuscles. If, however, they washed the red corpuscles free of serum, the cobra venom no longer had a haemolyzing action; but, on adding serum to the washed corpuscles, an addition of cobra venom produced haemolysis. Clearly something was contained in the serum which interacted with the venom to produce the result. Kyes showed that the activator is soluble in alcohol and in ether, and he finally identified the substance as lecithin. But cholesterolin, another lipid, has the property of counteracting the activating effect of lecithin on cobra venom. This antagonism of cholesterolin and lecithin points to some bio-chemical or bio-physical relationship between the two bodies. Moreover, this relationship as regards osmotic membranes and haemolysis has been experimentally put to the test by Pannucci. This observer constructed glass cells covered with a membrane impregnated with lecithin and cholesterolin; in these he placed haemoglobin solution, then suspended in the toxin solution; the haemoglobin behaved differently as regards diffusion according to the proportions of these substances in the membrane. If we regard the red blood corpuscles as consisting of a sponge-like protein stroma holding the haemoglobin in solution, the whole being covered with a membrane consisting of a properly adjusted complex of the lipid substances, cholesterolin and lecithin, then we may suppose that haemolysis occurs as a result of a chemical or physical disturbance of the balance between the cholesterolin and lecithin. This idea of an osmotic membrane to the red corpuscle was, as far as I am aware, first pointed out by Professor Schäfer in the section, *Blood*, *Quain's Anatomy*, 1893. In haemolysis the membrane is either dissolved by the action of a ferment or a physical change occurs in the membrane, by which it becomes permeable to the large haemoglobin molecules; whereas in its natural perfect state it will only allow the smaller ions Ca, Na, and K to pass through (Fig. 12). It is probable that all cells and unicellular organisms possess similar osmotic membranes, and that the lysis of these organisms depends upon physical or chemical changes in the osmotic membrane, which is termed a "periplasium." The importance of this question is obvious in regard to cytotoxicity, bacteriolysis, and protozoology, and it will become especially apparent when we come to the study of the Wassermann reaction of the deviation of the complement in the sero-diagnosis of syphilis.

In regard to the origin of lipoids, especially in patho-

logical conditions, it is necessary first to refer to an important paper by Munk just published. This observer has used the polarizing microscope to distinguish between fat and lipid in cells; the latter is doubly refractile when the Nicol's prism is rotated. Ambrose and Held made use of this method for determining the existence of the myelin sheath in the anterior and posterior roots of the embryo. Munk finds that the existence of lipid droplets in the cell is associated with dissolution of the nucleus and destruction of the cell. Rosenheim remarks that the phosphatides may form a link with the cell nucleus, which possibly obtain their necessary supply of P from this source. A lipid substance in great abundance, then, means cell dissolution, the nucleus highly charged with phosphates and the cell protoplasm breaks up into a lipid complex as a result of the nucleolysis and plasmolysis. It may be suggested that Levaditi's experiments show that the spirochaetes stimulate the fixed tissue cells to proliferate, and then, invading this bed of young cells rich in nucleus, they, by the action of some secretion or otherwise, cause these same embryonic cells to undergo lysis, thus providing the necessary pabulum for their own growth and proliferation. It is probable these young cells are more easily attacked than the older cells, and this may be the reason why the spirochaetes are found in such great abundance in fetal tissues, and why the fetal tissues, especially the liver, contains such an abundance of lipid substance serving for the Wassermann reaction, although chemically it does not differ from lipid substance which can be obtained from normal tissues.

We are now in a better position to consider the serum diagnosis by the Wassermann and other methods dependent upon bio-chemical changes induced in the body by the introduction of the syphilitic virus whereby immunity to future inoculation is effected; and which, in my opinion, lies at the root of the late degenerative processes occurring in the central nervous system, and which are collectively termed parasyphilis.

Although it has now been ascertained that the syphilitic virus induces in the body metabolic changes whereby larger amounts of lipoids occur in the serum, and also in the cerebro-spinal fluid in general paralysis and tabes, yet these same lipoids are found in the normal tissues and fluids, the specific character is manifested by quantity rather than quality. The substances which in haemolysis play the part of *antigens* are lecithins, combined with other substances, especially soaps (Rondoni and Sachs), and those which play the part of *antibodies* are possibly complexes of cholesterolin. Yet, although in describing the Wassermann and other methods and the evolution of the knowledge concerning the same the terms "antigen" and "antibody" will be used, yet it is better to state at once that they do not conform to the antigen and antibody of bacteriolysis, and that the deviation of the complement (or fixation of the complement) may possibly depend upon the presence of these two kinds of lipoids, which we have previously seen play such an important part in the action of cobra venom.

THE SERUM DIAGNOSIS OF SYPHILIS BY THE WASSERMANN METHOD.

To explain the principles of this method it is necessary to make a few introductory remarks regarding its origin. Bordet, in 1901, discovered the phenomenon known as the absorption or deviation of the complement. At about the same time Gengou discovered a similar phenomenon when working with precipitins. Wassermann, Neisser and Brück, Levaditi, Citron, Plaut, Stertz, and others have applied this method of the absorption of the complement of Bordet and Gengou to the diagnosis of syphilis by the existence of syphilitic antibodies and antigens in the blood serum and cerebro-spinal fluid of persons suffering with primary, secondary, and tertiary syphilis, as well as in the post-syphilitic, parasyphilitic, or late syphilitic affections—namely, tabes and general paralysis. The epoch-making experiment of Pfeiffer on bacteriolysis may be said to have afforded the foundation of our knowledge of the principles governing immunity. Bordet by his observations came to the conclusion that bacteriolysis by the serum of an immunized animal was due to the presence of two substances, the one destroyed by heat (thermolabile) present in normal serum, the other (thermostable)

a substance which resisted heat, and was only present in the body fluids and blood of an immunized animal. The former is called the cytase or complement, the latter the immune body or antibody (amboceptor, Ehrlich).

Fig. 12.—a, Normal blood corpuscle with osmotic membrane permeable to ions of Na, K, Ca. b, Chemical explanation of haemolysis by dissolution of osmotic membrane and escape of haemoglobin. c, Physical explanation of haemolysis by a bio-physical alteration of the osmotic membrane by which it becomes permeable to the large haemoglobin molecules.

antigen, but specific for each animal. Bordet has introduced the terms "antigen" and "antibody," the former to signify any substance which, when injected into an animal, will cause the production of an immune serum; the latter to denote the antagonizing substance produced and which is the essential for the immunizing action of the serum. Now, if either the antibody or the complement be not present, or be removed, the specific bacteriolytic or haemolytic action of the serum or fluid is lost. Again, if the antibody in the presence of the complement is linked up to the antigen, both the antibody and the complement will be inactivated. To find out if a given serum or fluid—for example, cerebro-spinal fluid—contains either the antigen or the antibody is by the experimental inductive method known as the *deviation of the complement*. How is this effected?

We require first to immunize an animal against the blood of some other animal; for this purpose the blood corpuscles of a sheep are injected into the circulation of a rabbit. The blood serum of the rabbit is thus made haemolytic to the corpuscles of the sheep by virtue of an immune body *plus* the normal complement or cytase. The latter can be removed by heating to 56° C. for thirty minutes without destroying the former. We have thus the immune body, which by itself will not dissolve the washed corpuscles of the sheep. If, however, we add the normal serum of a guinea-pig, the amboceptor or immune body

links up the complement or cytase and the corpuscles are dissolved.

The second part of the experiment is the deviation of the complement, or its neutralization, so that haemolysis no longer takes place when the serum of the guinea-pig is added to the immune body and the washed sheep's corpuscles. This is effected by the presence of both antigen and antibody in the fluid to be examined. The serum, or cerebro-spinal fluid, to be examined is mixed in varying dilutions with a watery solution of the liver of a syphilitic fetus, which will contain the antigen (lipoid). A small amount of the serum of a guinea-pig is then added, and the total volume made up to 2 c.cm. with saline solution. The series of tubes containing these mixed solutions are placed in an incubator at 37° C. for one hour, and then the sensitized blood corpuscles are added. (By sensitized corpuscles I mean washed sheep's corpuscles in immune rabbit's serum which has been heated.) The mixtures are again placed in the incubator for two hours at 37° C., then taken out and put on ice overnight. The next morning the amount of haemolysis in each tube is estimated (vide Fig. 13). If, on the one hand, antigen and antibody have been present they have united with the complement, and no solution of corpuscles will have taken place because the complement is fixed; if, on the other hand, the immune body (antibody) was not present then the complement (cytase) has remained free to act upon the sensitized corpuscles and lead to their solution. A control experiment, using a normal serum, or cerebro-spinal fluid, namely, one which contains no antibody, must be used at the same time.

In the hands of nearly all trustworthy and experienced investigators this method, introduced by Wassermann, has yielded most valuable results as a means of diagnosis. It is claimed even that it is more reliable than the Widal reaction for typhoid. Plaut obtained a positive reaction in 80 to 90 per cent. of undoubted cases of syphilis by this method. He found the reaction specific; it is not definitely present in a non-syphilitic individual; it enables a diagnosis of the constitutional disease to be made, but not of the organ affected. He did not obtain the reaction with the cerebro-spinal fluid in 25 cases of syphilis in which the nervous system was not affected, while the serum as a rule gave a positive reaction. This was not unexpected from what has already been said as regards the cerebro-spinal fluid and its secretion. It shows that the reaction depends upon the production of some substances by the

Fig. 13.—1, Cerebro-spinal fluid of general paralysis, showing the Wassermann reaction on removal from the incubator. 2, Ditto after standing overnight on ice. 3, Control with normal cerebro-spinal fluid, showing total haemolysis.

tissues of the nervous system themselves. The nature and origin of that substance will be discussed a little later, but reference will now be made to the remarkable unanimity of opinion of all those who have made experiments upon this subject as to the almost certainty with which the cerebro-spinal fluid of general paralytics, and to a less degree of tabetics, give this Wassermann reaction. According to Plaut the reaction may be negative with the cerebro-spinal fluid in cases of syphilis of the nervous system, but he obtained a positive result in 94 out of 95 cases of general paralysis with the cerebro-spinal fluid, and in every one of the cases the serum gave a positive reaction. In cases of cerebral syphilis the serum was usually positive and the cerebro-spinal fluid usually negative; in 70 to 80 per cent. of the cases of tabes the cerebro-spinal fluid gave a positive reaction. Citron, G. Meier, W. Fischer and G. Meier, Michaelis, Weygandt, Fleischmann and W. J. Butler and others have obtained similar positive results by this method.

At my suggestion, my assistant, Dr. Candler, in conjunction with Dr. Henderson Smith at the Lister Institute, has been engaged in applying this reaction to a number of my cases in the hospital and the asylum, with the following results: They have now examined the cerebro-spinal fluid of 100 cases, of which 94 were asylum cases and 6 were in general hospitals. Forty-six cases of general paralysis were examined, 41 of which gave a positive reaction by the Wassermann test, a percentage of 89.1. The reaction was not obtained in any of the control cases. Two cases of locomotor ataxia failed to give the reaction, but it may be noted that neither was in an active stage. A negative reaction was also obtained in a case of syphilitic meningitis in which the cell contents of the cerebro-spinal fluid were diminishing rapidly in numbers under specific treatment. It is also interesting to note that cases of tuberculous meningitis failed to give the reaction, although in one case the cerebro-spinal fluid contained a large number of leucocytes per cubic millimetre.

I wish here to acknowledge the kind assistance which has been rendered during this research by Dr. Robert Jones, the Medical Superintendent, and Dr. Hughes, Medical Officer of the London County Asylum at Claybury; Dr. Bond, the Medical Superintendent of Long Grove Asylum; Dr. Ingram and other Medical Officers of the London infirmaries; Mr. Gibbs, Surgeon at the London Lock Hospital; and Dr. Nepean Longridge of Queen Charlotte's Lying-in Hospital for Women.

For the purpose of diagnosis, therefore, especially of general paralysis, it is a very important addition to clinical methods. Since its application, however, many doubts have been cast upon the interpretation of the facts whether indeed the reaction is in any way due to syphilitic antibodies.

Levaditi and Yamanouchi made a study of the diagnosis of syphilis and general paralysis by the Wassermann method. The results of their researches are very favourable from the clinical diagnostic point of view. Levaditi and Marie have demonstrated the facts that normal liver can replace the syphilitic liver in the preparation of the antigen, and the cerebro-spinal fluid of general paralytics supposed to be rich in antibodies is devoid of spirochilic properties. These facts show that the sero-reaction in question, although clinically a specific test for syphilis, had nothing to do with syphilitic antigens and antibodies. Moreover, the active substances of liver extract, syphilitic or normal, contrary to the true antigens, are soluble in alcohol; and the sero-reaction can be obtained with bile salts and with lecithin, or with soap (Sachs and Altmann), cholesterolin and vaseline (Fleischmann), although more feebly. The sero-reaction of syphilis and of general paralysis is the same, and is not due to the intervention of antibody or syphilitic antigen in the usual sense of the word, and has no relation with the *Spirochaeta pallida*. Landsteiner and Porges have also demonstrated that the extract of the liver owes its particular properties for this reaction to the presence of lipoids and bile salts soluble in alcohol at 80° C. These products are found not only in the liver, but also in different organs of man and animals. Landsteiner, Müller and Potzl state that in syphilitic serum substances are present which in the general sense are not antisiphilitic bodies, but which bind up with certain constituents of normal

and syphilitic tissues. Moreover, they assert that the blood serum of animals infected with *T. equiperdum* and *T. gambiense* contain similar substances which they have called *Histafines*. Yet being a characteristic reaction, it is attributable to the presence in the serum and in the cerebro-spinal fluid of certain at present unknown compounds, which in the presence of bile salts, soaps and lipoids of the liver, precipitate and determine the fixation of the complement. Levaditi and Yamanouchi consider that these compounds arising in the organism itself may be a cholesterolin ester. Thus it will be seen that these authorities give a new interpretation to the phenomena of the Wassermann method, which, however, in no way militates against its value as a practical method of diagnosis.

They also assert that there are between normal serums and lipoids of the body and specific serums and liquids, only quantitative and not qualitative differences; the reaction of Wassermann is provoked by histogenic and not bacterial substances. They find, moreover, that lipoids serving for sero diagnosis not only exist in the liver but in other organs, the brain, the corpuscles of the blood, etc. They are probably complexes in which lecithin largely enters into the composition.

Levaditi, Ravaut, and Yamanouchi have proved that when syphilis leaves intact the central nervous system, although the serum gives a positive reaction, the cerebro-spinal fluid does not, and this is what one would expect. It is, however, different when the central nervous system is affected even in a slight degree. The cerebro-spinal fluid can then acquire properties which enable it to yield the Wassermann reaction. In fact, in the four cases out of the many examined presenting nervous symptoms, which were neither tabetics nor paralytics, the fluid has twice given a positive reaction, although quite feeble. The method of fixation of the complement would up to a certain point then serve for the early diagnosis of syphilis, especially when the brain is affected.

The researches of the above-named authors show that there is not any parallelism between the results furnished by the cytological examination and those obtained by the Wassermann method. The leucocyte reaction may be very marked in certain secondary specific cases without the cerebro-spinal fluid being in the least able to fix the complement. Such was the case in one of my patients with well-marked syphilitic cerebro-spinal meningitis. This patient was a woman, aged 34, admitted under my care at Charing Cross Hospital as a case of tabes; upon examination I diagnosed cerebro-spinal syphilitic meningitis (pseudo tabes). Lumbar puncture gave 370 lymphocytes per c.mm. She was put on mercurial inunction, and in a fortnight she had greatly improved; the lymphocytes were now only 70 per c.mm. A fortnight later the lymphocyte count was 20 per c.mm., and she was well enough to be discharged, nearly all the symptoms having disappeared. The Wassermann reaction was negative on the last two occasions when lumbar puncture was performed; it was not tried in the first instance. The existence of numbers of lymphocytes in the spinal canal does not necessarily entail the appearance of substances which in the presence of lipoids engender the phenomenon of Wassermann. Marie and Levaditi, and we at Claybury, found that there is a parallelism between the rapidity of progress of general paralysis and the degree of intensity of the Wassermann reaction; no doubt, therefore, there is a connexion between the breaking down of nervous substances (destructive metabolism) and the amount of this complex lipid substance, with which probably the reaction is associated, and upon which it, in a measure, depends. I have been attempting to ascertain the chemical nature of this substance, but my results are not yet sufficiently advanced to make any definite statement. However, I have found that the blood and cerebro-spinal fluid in parasyphilitic affections contain a marked excess of lipoids, inorganic salts, and splitting products of the phosphatides; and that this excess is proportional to the intensity of the disease. I have also found that a cerebro-spinal fluid which gives a positive Wassermann reaction, after removal of the protein content by precipitation with alcohol, fails to give the reaction. I am, therefore, in agreement with Noguchi, who, working on the relation of protein, lipoids, and salts to the Wassermann reaction, has come to the following conclusions:

1. "The high value in respect to complement binding exhibited by blood serums from syphilitics and spinal fluids from general paralysis is associated with an excessively high content of globulin, but there does not exist a direct quantitative relation between the two. Cases of secondary syphilis which have been under prolonged and proper medication do not exhibit the globulin increase and usually fail to give the Wassermann reaction. The active substances entering into the Wassermann reaction are precipitable with the globulin and chiefly with the euglobulin fraction of the fluids.

2. "Temperatures of 70° to 76° C. destroy the active substances. Exposed to sunlight the active substances deteriorate slowly. A photodynamic substance such as eosin, under the direct influence of the sun, brings about their complete and rapid destruction. This effect does not occur in the dark. The active substances are subject to tryptic and pepsic digestion and are destroyed by weak acids and alkalis.

3. "The active substances in the blood serums and spinal fluids cannot be separated from them or from the globulin precipitate by alcohol.

4. "There are contained in the alcoholic extracts of normal and syphilitic blood and organs certain acetone soluble lipoids which possess high antigenic values for the Wassermann reaction. Cholesterol is inactive and the bile salts less active than the lipoidal bodies.

5. "Sodium cholate is about as active as sodium taurocholate and glycocholate, but neurin and choline are inactive."

Porges and Meier found that by addition of lecithin certain substances contained in syphilitic serum are rendered evident by a flocculent precipitate, and they have employed this method in place of the deviation of the complement method. But it is generally thought that this precipitation method is not so specific as the Wassermann method; moreover, Neubauer, Porges, and Salomon were able to show that syphilitic serum only behaves stronger in this respect than normal serum. Fritz and Kren found that the lecithin test is not absolutely reliable, for non-specific diseases as tuberculosis, lepra, etc., give a precipitation; still less reliable is the test with glycocholate and taurocholate of soda. In respect to the Klausner reaction of globulin precipitation it was found that it was more uncertain than the lecithin and bile salts flocculation.

Neisser, Bruck, and Stern's investigations are of importance, for they have made a large number of experiments with apes and anthropoid apes, as well as observations on human beings. They conclude that the antigens are not identical with the living virus, nor of the same substance. They do not consider that mercury and atoxyl cause a destruction of the antigen, but that treatment by these drugs injures or destroys the spirochaetes. Moreover, it has been found that antibodies exist normally in small quantities in some of the lower apes; it has so far not been found in the higher apes; it is therefore not a new product in syphilis, but it is enormously increased in quantity in this disease. They consider that the serum diagnosis researches prove a direct association of syphilis, tabes, and general paralysis. Immunity to reinoculation occurs when the virus has become generalized in the blood and lymph (Neisser). It is probable that the generalization of the virus engenders simultaneously changes in the properties of the serum, by which changes it becomes capable of giving the Wassermann reaction and preventing reinoculation.

There are a number of other reactions which show that a profound bio-chemical change occurs in the blood in constitutional syphilis. Thus Klausner has shown that distilled water added to syphilitic serum causes a precipitation due to the amount of a precipitable globulin which syphilitic serum contains. Fornet and Schereschewsky have shown that the serum of paralytics and tabetics exclusively give with the serum of syphilitic patients a positive precipitin reaction. It is claimed, therefore, by them that this observation proves the syphilogenous origin of these two diseases.

The simpler method of Noguchi, to which I have been giving attention, consists in boiling for a few seconds 0.2 c.cm. of the cerebro-spinal fluid with 0.5 c.cm. of 10 per cent. butyric acid solution of 0.9 per cent. sodium chloride, and then adding 0.1 c.cm. of normal solution of

caustic soda, and boil again very briefly. A flocculent precipitate is obtained in parasyphilitic affections.

Dr. Noguchi informs me that he has obtained positive results with the cerebro-spinal fluid of cases of general paralysis, tabes dorsalis, cerebral syphilis, cerebro-spinal syphilis, spinal syphilis, tertiary syphilis, and some few cases of secondary syphilis. Negative results were obtained in cases of alcoholic psychosis, dementia praecox, imbecility, idiocy, and other non-specific diseases. However, as one would expect, the fluids from cases of tuberculous meningitis, pneumococcal meningitis, and epidemic cerebro-spinal meningitis gave a large precipitate. The slightest blood contamination of the fluid renders the test valueless. Should the results be constant, this method will be of great value on account of its simplicity. It is due to the presence of a globulin; it has before been remarked that there is a parallelism between the presence of albumin in the cerebro spinal fluid and the Wassermann reaction.

Summary.—The original method of Wassermann is the most complicated, but is regarded by the majority of investigators as the most specific and reliable. Whatever may be the explanation of the facts, all the evidence goes to prove: (1) That these methods in the hands of competent observers afford a valuable means of diagnosis, and are especially useful when applied to the cerebro-spinal fluid for the determination of the existence or not of general paralysis. (2) That similar substances, whether antibodies or not, occur in the serum of syphilitic and parasyphilitic persons in such quantities as are not found in the serum of normal persons or in the serums of people suffering with other diseases. (3) That similar substances are found in the cerebro-spinal fluid of tabetics and general paralytics, and the amount of those substances which cause a deviation of the complement or a precipitation is in proportion to the activity and length of duration of the disease; that these substances are of tissue origin, or arise from tissue destruction caused in some way by the action present or past of the syphilitic virus. (4) It is probable that the syphilitic virus excites an increased loosening of complex lipid substances, containing lecithin and cholesterol, etc., from the red corpuscles and cells of the body. (5) That this prevails through life, and in certain cases of syphilitic infection—namely, general paralysis and tabes—the central nervous system, which under ordinary circumstances is protected against the loss of its lipid substances, takes part in the process, and this is manifested by the presence of lipid and globulin in the cerebro-spinal fluid which acts as the antibody in the reaction. This lipid complex, as well as globulin, increases in amount as the process of neuronic decay proceeds. It is probably owing to the presence of these substances that the granulation of the ventricles, so characteristic a feature of general paralysis, arises as a result of stimulation to proliferative hyperplasia of the ependymal epithelium. Choline may also be present owing to decomposition of lecithin, but this may occur in any active degenerative process of the myelin, and is not pathognomonic of any particular disease.

Other lipoids of the phosphatide group are present usually in considerable amount and in proportion to the extent of myelin destruction and dissociation. I have pointed this out in the *Archives of Neurology*, vol. ii, 1902, p. 304, where, after referring to the work of Flexner, Noguchi, and Kyes on cobra venom, "I stated that the products of degeneration of nervous tissues in general paralysis are numerous, and consist not only of choline, but also of a number of bodies of the lecithin group, being various derivations of 'protagon.' Choline is the most easily separable and recognized physiologically and chemically, and it is possible that the products of degeneration vary according to the cause and nature of the destructive process. Still, there is no evidence to show that these products of degeneration can *per se* produce the clinical manifestations and morphological changes indicating neuronic irritation and destruction of general paralysis; otherwise we ought to get these changes in other diseases, also destructive lesions of the nervous system. Therefore I think it may be conceived as possible that there is a latent toxin in the blood which combines with endo-complements the products of deranged neuron activity, producing locally (this is, where the neuron metabolism is deranged either by stress, circulatory deficiencies, or hereditary physiological or anatomical defects) an active neurolysin proportional to (a) the amount of latent toxin in the blood, and (b) the amount of endo-complement produced by the deranged neuron metabolism."

Blumenthal states that he has found that the blood of syphilitic persons, also tabetics and paralytics, contains

a large increase of lecithin as compared with the normal. He finds also an increase of lecithin in the faeces in tabes and general paralysis, and a great decrease in the bone marrow. He considers that tabes and paralysis are associated with a progressive impoverishment of the body in lecithin. It is more probable that there is an impoverishment of lipoids.

ON THE EARLY DIAGNOSIS OF CANCER OF THE TONGUE, AND ON THE RESULTS OF OPERATIONS IN SUCH CASES.*

By HENRY T. BUTLIN, F.R.C.S., D.C.L.,
 CONSULTING SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

In the first week in January the BRITISH MEDICAL JOURNAL published the results of my operations for cancer of the tongue on 197 patients. They were, after the paper had been put together, brought up to 200. The results remain very much the same, for no further death occurred as the result of an operation, and a couple of cases have been added to the list of "successful cases." A medical journal, commenting on my paper, expressed surprise that the total number of cases was so small, and, while believing that I had perhaps performed more operations for cancer of the tongue than any other British operator, evidently thought that some of the Continental or American surgeons must have operated much more frequently. I own that, when I put all my cases together, the number seemed to me small for five-and-twenty years' work of a surgeon whose name has been associated with cancer of the tongue for a great part of that time. So I looked to see what had been done elsewhere. I think that Professor Kocher, in a longer series of years, has not operated on more than 120 to 140 patients. Billroth had comparatively few cases. And no other Continental operator seems to me to have exceeded 100 cases; few of them have nearly approached that number. On the other hand, I think Mr. Whitehead, whose name was justly held in the greatest esteem throughout the world for his operation for cancer of the tongue, probably operated on quite as many patients as I have done.

The limited number of cases which come under the care

of any one surgeon led me to wonder how frequent cancer of the tongue is; and, as I could not find any definite published information on this matter, I wrote to Dr. Tatham of the General Register Office. With his usual courtesy and readiness to afford assistance to those who are studying death-rates, Dr. Tatham at once sent me information to the effect that during the seven years, 1901-7, there died in England 5,253 persons of cancer of the tongue, making a yearly average of 750. I suppose another 50 to 70 cases may be added to account for the persons who are treated successfully, but I am afraid that is rather a large estimate. Still, it may probably be roughly reckoned that about 820 people suffer from cancer of the tongue in England every year, and that 750 of them die of the disease, either with or without operation. Surely, a result not very creditable to surgery! Yet, I think we in this country probably show as good or better results of our operations than the surgeons of any other country. For the feeling on the Continent and in America is absolutely pessimistic regarding cancer of the tongue. One of the most distinguished of the American surgeons wrote recently to tell me that, in about 36 cases, he only knew of 2 definite cures. And one of the chief Austrian surgeons told me in September that he did not remember ever to have had a successful case. Professor Kocher appears to be one of the very few surgeons who is really hopeful over his results.

For a long time it has been evident that we must operate earlier if we are to hope for better results. Billroth spoke of the importance of early diagnosis years ago, but no one has really worked at it until quite recently. Circumstances were against us all: such as the difficulty of persuading doctors and their patients to submit to operations for what were not certainly known to be cancers; the imperfect examination of the reputed precancerous conditions when they had been from time to time removed.

Fortunately, five years ago Dr. Bashford, of the Imperial Cancer Research, asked me for specimens of early cancer of the tongue; and, still more fortunately, the first material which I gave him, and which I believed to be a precancerous condition, proved to be typical epithelioma. This roused my suspicion regarding precancerous conditions and led me to urge persons suffering from what appeared to be almost trivial conditions to submit to operation. I suppose I have become a greater master of the art of persuasion than I was ten or more years ago. But sure it is that I have succeeded in collecting a dozen cases of very early cancer and have had them all carefully drawn; and the microscopical examination has been made by the Imperial Cancer Research.

And, again, happily the BRITISH MEDICAL JOURNAL has published excellent reproductions in colour of twelve of my drawings, and these have been sent out all over the world, so that the knowledge of the appearance of early cancer of the tongue has been very widely spread. This is a great tribute to the liberality of the British Medical Association and to the enterprise of the Editor of the JOURNAL and the General Manager.

The conditions which are represented may fairly be divided into five classes:

1. A little plaque like a hard sore, smooth and polished, but neither ulcerated nor excoriated.

2. The transformation or replacement of a simple ulcer by a cancerous ulcer, which only differs from the simple ulcer by feeling a very little stiffer and a very little firmer.

3. The transformation of an entire plaque of leucoplakia into a plaque of cancer. The difference is marked by very slight thickening, a denser white, and furrowing or fissuring in various directions, but without excoriation or ulceration.

4. The transformation of one small area of a leucoplakic tongue into cancer, only marked at first by very slight and superficial hardening.

5. A white wart growth or compound wart, neither broken or ulcerated, and feeling at first as if it were fixed to the mucous membrane, and quite superficial.

There are other conditions in which cancer of the tongue begins, but these seem to me to be the most frequent and the most typical.

I am sure the Fellows and Members would like to know the results of the surgical treatment of these early conditions. There are twelve cases of which I have drawn

* Delivered before the Royal Society of Medicine, February 12th, 1909.

ings, and two cases which occurred before Miss Mabel Green had begun to draw for me. I include these two cases because they have already been referred to in the BRITISH MEDICAL JOURNAL, and are of especial interest.

The incisions only aimed at free removal of the cancer, with a sufficiently wide area of surrounding healthy tissue. Of the 14 patients, 3 are dead—one of nephritis and heart failure a year and a half after the operation, and without recurrence of the cancer; one of affection of the cervical glands without recurrence in the mouth; and one, who was operated on for cancer of the right border of the tongue, of cancer of the left border of the tongue, which he would not allow to be cut out until the glands were diseased beyond the reach of operation. The tongue between the two borders was quite healthy. The remaining 11 patients are alive and well at periods of eight months (1 case), one to two years (2 cases), two to three years (2 cases), three to four and a quarter years (6 cases). One patient of the last group, for whom I removed the left half of the tongue to very far behind the disease, and the lymphatic glands, suffered a year later from a fresh outbreak of epithelioma on the tip of the stump, where it was constantly rubbing against a large lower molar tooth, decayed and isolated. At the present time, three years after the removal of this second cancer, he is quite well. It may therefore be claimed that there is not a single case of local recurrence of the disease in any of the 14 patients, although 8 of them lived for three to more than four years after the operation. The glands were removed in 9 of the cases.*

The extent of the operation was generally quite out of proportion to the size of the cancer. But this was in order to remove long-standing leucoplakia and chronic superficial glossitis, from which the patient had in most cases suffered for years. On the other hand, there were two cases in which the cancer was removed between two elliptical incisions which were only just wide of its borders. In both these cases the disease was of very limited extent. The actual cancer in one of them measured about $\frac{1}{2}$ in. across by $\frac{1}{4}$ in. in thickness. It was one of the smallest cancers of the tongue which I have ever seen. The incisions passed pretty deeply into the muscular substance of the tongue. There was never any local recurrence, and the defect in his tongue was so trivial that his medical attendant, who had not been told of the operation, examining his mouth more than three years later to discover the source of infection of enlarged glands from which he was then suffering, did not perceive that his tongue had ever been operated on. Yet he died of epithelioma of his glands due to that tiny cancer. I have brought sections of another very small cancer of the tongue which was cut out by a very moderate operation, but which killed the patient through his glands, although it never recurred in his tongue.

At this moment, it would scarcely be too much to say that the air is charged with the emanations of radium. We are told that epithelioma of the tongue can be cured by radium. Had I been asked my opinion on this question a month ago, I should have said that, although two or three people in different parts of the world have claimed this power for radium, the general belief is that rodent ulcer is the only variety of malignant disease which radium is competent to cure. And I should have added that the only case of epithelioma of the mouth in my own practice to which radium had been applied (by the most skillful man with the best material) had ended disastrously. But I have, within the last few days, seen a case in which a typical epithelioma of the inside of the cheek is so much better, under the application of radium, at the end of four months that it looks as if it would be quite cured. And this has apparently been accomplished without inflammation or sloughing or profound ulceration of the disease. I understand that the radium in this case was applied by means of the disc. As this epithelioma was about $1\frac{1}{2}$ in. in diameter and ulcerated all over, when I saw it four months ago, there seems no reason to doubt that small epitheliomata of the tongue may be removed by radium, probably with a better scar than would be left by any

other efficient agent. But, having said this, it must not be forgotten that the removal of the primary disease is only part of the cure of epithelioma. Even the smallest, the youngest, and apparently the most insignificant epithelioma of the tongue is capable of affecting the lymphatic glands, as the cases I have related show. So that, unless radium is discovered to possess a far-reaching influence, spreading from the seat of the primary disease to the associated lymphatic glands, I am afraid that the surgeon must still occupy an important place in the treatment of epithelioma of the tongue.

UNNA'S METHOD OF TREATING ULCERS OF THE LEG.

By GEORGE PERNET, M.D.

WITH reference to the abstract of a German paper on Unna's bandage published in the *EMITOME* of January 16th, 1909, par. 33, I should like to point out that Dr. Hecker has missed an important point in the mode of application. I have treated a good many varicose ulcers of the leg by Unna's method, especially when I was out-patient assistant to Sir Victor Horsley at University Hospital. At that time I looked up Dr. Unna's original paper on the subject and carried out the method on the lines laid down by him, and I may add with very gratifying results.

In as few words as possible, the following is the *modus operandi*:

The ulcer itself is cleaned up with a 1 in 2,000 solution of mercury perchloride. Iodoform is then dusted or blown on to the floor of the ulcer only. In one instance only of the hospital series first treated (1891-2) by me in this way did I see iodoform dermatitis produced, but that was characteristic and rather severe. Some of the substitutes for iodoform are therefore to be preferred for this and other reasons.

Unna's gelatine paste, liquefied in a hot water bath, is then painted on the parts surrounding, but not on the ulcer itself, well beyond the latter, and wherever there is redness or discoloration of the leg. A good formula is that of the *U.C.H. Pharmacopoeia*:

Zinc oxide	10 parts
Gelatine	15 "
Glycerine	30 "
Water	45 "

Fig.: Soak the gelatine in the water for two hours; add the glycerine; apply a gentle heat till dissolved; stir in the zinc oxide to a smooth consistence; allow to cool.

Two or three double-headed 3 in. muslin bandages (in one piece rolled from either end, and not bandages made by stitching the ends of two ordinary bandages together) are next required. Muslin, such as is used for plaster-of-Paris work, answers very well. I now use sterilized bandages of this kind, put up separately. A two-headed bandage is wrung out in warm (sterilized) water, and the middle of the bandage is then placed on the leg opposite the ulcer, the two heads being firmly held one in each hand. The first turn is then made with pressure vigorous enough to reduce the diameter of the limb, the bandage being brought well over the ulcer. This way of employing the two-headed bandage is the crux of the whole matter, and the central idea of the method, and is a very different thing to bandaging from the toes upwards as recommended by Dr. Hecker. The bandage is then taken round the leg, with firm pressure, especially over the actual ulcer, allowing the turns to take one more or less where they list, the two hands being used for this purpose, and the turns being evenly applied, an easy matter, the bandage being wet. Meanwhile the liquefied paste is painted on the bandage as it is wound round the limb, either by the patient or an assistant. Two or three bandages can be used in this way, a few figure-of-eight turns being taken under the foot in order to fix. The result is a splint, which allows patients to go about their work as usual. If there is a great deal of discharge from the ulcer the bandage will require to be changed the next day, but after the first few days the bandage can be left on for several days together.

The method in its principles is really the same as our English one of strapping ulcers (Baynton's), but it is more

* I am not sure whether the glands were removed in another of the cases. Two of the patients were operated on by Mr. Percy Power at St. Bartholomew's Hospital, and I was present at the operations. Mr. Power thinks that he removed the glands of one of these patients (the man who died of nephritis) a few days later. But the notebooks do not contain a record of the operation.

elegant and more efficacious. The point to bear in mind is the firm pressure on the edges of the ulcer in order to flatten them down. I repeat this because what is called Unna's method of treating *ulcus cruris* is frequently performed in a very perfunctory and inefficient manner, the idea which underlies it being entirely overlooked.

I have obtained very good results by this method; in some cases, indeed, excellent. In the case of women especially, such as landresses, charwomen, etc., the patients are able to follow their occupation with comfort and earn their living, so precarious at the best of times—an important item for these poor people under existing social arrangements. Of course, wherever possible, I agree with Dr. Hecker when he says the bandages should be applied "before the patient leaves bed." Personally, when ordering ordinary bandaging of the legs from the root of the toes upwards to support varicose veins, I have for a good many years recommended patients to do this before they got up in the morning, namely, before the effects of gravity in the vertical position came into play.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

X-RAY TREATMENT IN VENEREAL SORES AND BUBOES AFTER OPERATION.

THE patient is placed on his back with his head raised. A strip of lead, 9 in. wide, with a central hole, is placed over the penis; above and below this is placed foil covering the body from the neck to the knees. A small piece of lead, which has an opening just a little larger than the sore, is placed over the penis, so that the sore is exposed; the patient, using both hands, steadies the foil and the penis; the hands and arms are covered with foil. The tube is 6 in. distant from the part. The tube must be soft (about 2 in.); the amperage about, but not exceeding 4. The exposure is of five minutes' duration. After four days, if there be no reaction, a further exposure of five minutes is given; after four more days, if there still be no reaction, a further five minutes is again given, continuing until a reaction is produced, when the exposure is reduced by one-half, other conditions remaining the same, and the interval is extended to seven days. The applications are continued until the sore heals, and stopped directly the first signs of radio-dermatitis are noticed. The patient should be made to understand thoroughly the value of absolute cleanliness.

In the case of buboes which have been operated on the method and exposure are precisely the same—a small piece of foil surrounding the part and protecting the tissues in the vicinity.

All the lead in actual contact—that is, the "apron" and the small pieces—are boiled daily after use, the larger pieces once a week, unless they get soiled in any way. Each patient has a sterile piece of lead in contact for each exposure. Iodoform, calomel powder, or other dressings must be removed from the part to be treated before exposure, as they absorb the x rays. The usual dressing subsequently employed is sterilized gauze for open buboes, mercury perchloride (1 in 2,000) on lint for venereal sores.

The results have been extremely valuable. The healing of the chancre is considerably accelerated, in all probability in less than half the time as contrasted with any other local measures.

In the case of venereal sores the tendency to suppuration or of hyperplastic matting of the nearest lymphatic glands is also reduced, a matter of extreme importance as regards the efficiency of the soldier. The healing of large operation wounds after excision of broken-down glands and scraping of the babo is markedly accelerated, the suppuration is lessened, and more healthy granulations make their appearance.

I have no knowledge of x rays having ever been used in the above class of cases.

H. C. FRENCH, Major, R.A.M.C.

Royal Herbert Hospital, Woolwich.

AURAL IMPACTION OF A CHERRY STONE FOR TWENTY YEARS.

When I first saw the patient in the following case—as a locumtenent after her confinement—I noted a discharge

from the right ear. Just inside the external meatus, and completely occluding the canal, was a rounded mass bathed in pus, which I thought might be a large polypus. Having no instruments with me I postponed closer examination, simply giving instructions for the ear to be syringed with warm boracic lotion three times daily. On my next visit, two days later I found that, the ear having been very painful, poultices as well as syringing had been used, and the body I had observed but not identified had been extracted in two halves; one had come away with the poultice the previous evening, the other the morning of my visit. The former had been thrown away. The latter I saw and examined. It was half a cherry stone covered with a loosely adherent membrane and cartilaginous in appearance. The interior was honeycombed and bathed in pus. Both pieces came away without any sort of assistance—simply adhering to the poultices. The patient's mother, who was present, gave me the following history:

When aged 5—or twenty years before I saw her—the patient pushed a cherry stone into her ear, and immediately told her mother. It was not far in, and the mother tried to extract it with a pin, but only pushed it deeper. For the next few years the stone remained visible, and caused periodical attacks of earache. Frequent attempts were made by the mother to extract it by means of hairpins and the like; but it got pushed further in by degrees, and eventually could not be seen. No medical man was consulted. The stone continued to cause deafness and frequent attacks of earache, but there was no discharge from the ear until the seventh month of her recent and second pregnancy. The earache then became more severe and persistent and a slight purulent discharge appeared.

During her subsequent delivery—that after which I first saw her—the patient "felt something burst" in her ear during a pain, and the discharge soon became more profuse, the earache continuing; sixteen days later the stone was extracted as stated. It would seem that it had been dislodged from its deep position, and possibly broken, during the straining of childbirth, and, once loosened, was gradually forced outward by the pus behind it, until finally, with the aid of syringing and poultices, it came out altogether.

Bournemouth.

J. E. ESSELMONT, M.B., Ch.E.

REFLEX COUGH.

A few days ago I was called to see a boy whose parents had lately come into the district.

The history was that for the last eighteen months, following an attack of whooping-cough, he had suffered from a distressing cough, so severe that he had been sent home from school "as he kept the other boys awake at night." The patient had been under treatment the whole time in various parts of the country. On examination nothing was found in the chest, nose, throat, or mouth to account for the cough, which was of a typical reflex type. The right ear, however, showed a quantity of cerumen, and on gently syringing I was able to extract a large mass, embedded in the centre of which was a complete clover flower about the size of a marble. This foreign body had given rise to no ear symptoms nor could I fix the date of its entry. The cough ceased within a few hours and the boy has returned to school.

My only excuse for reporting this somewhat trivial case is to draw attention to the necessity of a systematic examination of all organs which may be irritated reflexly and so give rise to symptoms which refuse to yield to routine treatment.

Limpfield. J. REGINALD BENTLEY, M.B., B.C. Cantab.

WE are requested by Dr. Grosz, Secretary-General of the Sixteenth International Medical Congress, which is to be held at Buda-Pesth from August 29th to September 4th this year, to call the attention of those who propose to take part in the proceedings of the Congress to the regulation that the manuscripts of their communications should be dispatched by February 28th, 1909, at latest, to the office of the Congress, VIII Esterházy-utca 7, Buda-Pesth (Hungary). We would also remind our readers that the subscription to the Congress is twenty-five crowns in Austro-Hungarian currency, which sum may sent by post-office order to Professor Dr. de Ellischer, Treasurer of the Congress, VIII Esterházy-utca 7, Buda-Pesth.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

BIRMINGHAM BRANCH.

PATHOLOGICAL AND CLINICAL SECTION.

Birmingham, Friday, January 29th, 1909.

Professor LEITH in the Chair.

Chondro-Sarcoma of the Humerus, removed by Berger's Operation.—MR. GEORGE HEATON showed a patient after Berger's interscapular thoracic amputation for a chondro-sarcoma of his shoulder:

The patient was a youth aged 21, who had noticed an enlargement of his left shoulder for ten years. The growth had rapidly increased in size during the last twelve months. The tumour measured 23 in. in circumference. It was a large irregular-shaped chondro-sarcoma, growing from the upper epiphysis of the humerus. In places the mass was undergoing a mucoid softening. The head and upper third of the bone had been almost completely destroyed by this growth. The shoulder joint was not implicated, but the mass had become fixed to the scapula, rendering amputation at the shoulder joint itself impossible. The tumour itself was shown and microscopic sections of it exhibited. The patient made an excellent recovery, and had since the operation increased in weight so much that when he left the hospital his weight without his entire upper extremity exceeded his weight when he entered the hospital, and before the operation.

Acute Toxaemia from Liverpool Rat Virus.—DR. OLIVE ELLWOOD read a note on a case of acute toxaemia caused by the Liverpool rat virus:

The patient, aged 13 years, was seen to swallow a piece of bread 1 cub. in. in size, soaked in a solution of the Liverpool rat virus, obtainable at any chemist's. Exactly twenty-four hours after the accident the child became suddenly cold, clammy, and drowsy. Within half an hour the following symptoms had declared themselves: Unconsciousness, combined with irritability on being touched; pyrexia to 99.8° F.; increased pulse rate to 150-160 per minute. At the end of twelve hours the temperature was 102°, pulse 160, breathing slightly stridorous, unconsciousness and irritability were maintained, and fibrillar twitches of the face and hands developed. Urine was in the bowels were considered; there were no abdominal pains nor cramps, and no vomiting, and, except for the latter feature, the clinical picture resembled that of the stage of irritation of acute meningitis in a child. At the end of twenty-four hours from the onset the temperature was 99°, and the symptoms were commencing to abate, and at the end of thirty-six hours recovery was complete. One stool was passed during the attack; that was apparently normal. The symptoms in the case were mainly cerebral, and thus differed materially from the cases reported in the BRITISH MEDICAL JOURNAL of November 21st, 1908, which were typical instances of acute gastro-enteritis. In these cases, however, considerable doubt seems to be present as to whether a specific infection of the food taken with the virus had really taken place.

Red Infarct of Heart.—DR. MILLER showed a specimen of red infarct of the heart, with microscopic preparations:

The case was that of a man aged 56, who was admitted to the General Hospital under Dr. Saunders, suffering from severe pain in the region of the heart, difficulty of breathing, and swelling of the feet. He had been taken ill suddenly some two months previously. He had never suffered from heart symptoms previously, but he had had four attacks of influenza. On examination his heart was found much enlarged. There were no distinct murmurs. The pulse was very irregular and intermittent. At first the patient improved under treatment, but then the oedema became more marked, and spread all over the body; he suffered severely from sleeplessness, pain, and difficulty in breathing, and died six weeks after admission. At the necropsy the heart was found to be much enlarged, weight 3½ oz. All the cavities were dilated and their walls hypertrophied. The mitral valve showed chronic thickening, and admitted four fingers easily. There was a softening thrombus at the apex of the left ventricle. The aortic valves and the first part of the aorta were fairly healthy; the arch and the descending portion showed well-marked atheroma. Both coronary arteries showed well-marked fatty and calcareous atheroma. The left coronary was completely blocked by a mixed thrombus which was adherent to its wall practically from its commencement. On cutting into the wall of the left ventricle a large area of a deep red colour and hard consistence was found in its anterior part. The remainder of the muscle was pale yellow in colour. On microscopic examination the red area showed necrosis of the muscle fibres indicated by the failure of their nuclei to take on haematein, and by the way in which they stained with van Gieson's counterstain. The spaces between the fibres were occupied by large numbers of red blood corpuscles, practically unaltered. In places the muscle fibres had disappeared almost altogether,

leaving spaces or vacuoles occupied by red cells and leucocytes. The yellow areas of muscle showed a similar appearance, but without the red cells. There appeared also to be a fairly diffuse but not very marked increase of fibrous tissue in the myocardium. A specimen stained for fat showed the reaction in the muscle bundles immediately under the endocardium. There were also numerous fine fat globules between the muscle fibres. The lung showed large numbers of infarcts, one of which occupied the whole of the left lower lobe. The remainder of the organs showed chronic venous congestion.

Pneumonia in One Family.—DR. STACEY WILSON gave the clinical history of a series of cases of pneumonia occurring in the same family at the same time. There were five children in the family, and all developed symptoms of severe bronchopneumonia, two of them dying. Dr. MILLER showed microscopic preparations and cultures from one of the fatal cases in the above epidemic. At the post-mortem examination the lungs were found to show the characteristic appearances of bronchopneumonia. Cultures were made from the lung substance, and an organism was isolated with the characters of the influenza bacillus. The organism only grew upon blood agar in the form of minute isolated colonies practically invisible to the naked eye. Microscopically the germ was a minute bacillus, which lost the stain with Gram's method. A similar organism was demonstrated in stained sections of the pneumonic lung.

SPECIMENS.

Dr. FUSLOW showed the following specimens:

1. **Broad Ligament Cyst with Twisted Pedicle.**—The cyst, which formed a tumour of the size of a six months pregnancy, was removed from a single woman, 22 years of age. She had noticed a swelling of the abdomen for twelve months; there had been severe pain, which commenced suddenly for six weeks before admission. The twisting was through two complete turns, and involved the ovarian ligament; the ovary was swollen to the size of a foal's egg, and was removed with the cyst. On section its interior showed several extravasations of blood.

2. **Uterine Fibroid and Pyosalpinx.**—This was removed from a sterile married woman, aged 40. The fibroid, 4 in. in diameter, occupied the anterior wall of the uterus, the uterine cavity skirting round the growth. In the outer half of the left tube was a swelling containing inspissated pus. The patient had complained of severe menorrhagia and dysmenorrhoea.

3. **Blood Cysts of Ovaries.**—This specimen was removed from a multipara, 28 years of age, who had had three severe attacks of pelvic peritonitis during the past nine months. She was admitted at the end of the third attack. There were fixed tender swellings on each side of the uterus and double pyosalpinx was diagnosed. On opening the abdomen the uterine appendages were found to be densely adherent, and were with difficulty enucleated; the appendix was also involved, and was removed. The specimen shows dilatation and occlusion of both tubes, but the larger part of the swelling is formed by the ovary, on each side, the one on the right side containing a blood-filled cyst 1½ in. in diameter. The pathological report was as follows: The tube shows chronic inflammation, and its wall is continuous with the substance of the ovary. There is a cyst in the outer part of the ovary, full of blood clot, and the lining of the cyst consists of layers of lutein-like cells, the condition being one of haematoma of a corpus luteum.

4. **A Uterus Containing a Large Number of Small Fibroids, in all Positions, in its Walls.**—The whole constituted a tumour as large as a four months pregnancy, and was removed by vaginal hysterectomy, combined with dissection of the uterus, from a woman who was blanched by severe haemorrhages.

All the patients made good recoveries.

Sir THOMAS BARLOW, M.D., President, in the Chair.

Cancer of the Tongue.

Mr. H. T. BUTLIN read a paper on early operation for cancer of the tongue, which is printed in this issue of the BRITISH MEDICAL JOURNAL (see p. 462).

Mr. BARKER said that Mr. Butlin's work should stimulate all surgeons to increased activity in the removal from the tongue of small masses which are suspected to be cancerous; but in all such cases ought they to remove the glands? He did not like to say anything to prevent surgeons from removing the glands in these operations, but he had had so many cases where he had not removed the glands, and where recurrence had not taken place, that

he felt it only right to bring the matter forward. He emphasized the point that the term "cancer of the tongue" included many types varying in degree as regards malignancy.

Mr. W. G. SPENCER considered that a patch on the tongue affording any suspicious induration should be cut out and examined microscopically; if small-celled infiltration was found lying below the epithelial downgrowth, then the case, in his opinion, was cancerous, and if the infiltration was spreading down through the muscle fibres, then the glands would be affected.

Mr. CLUTTON agreed with Mr. Butlin's views.

Mr. BOWLEY said that he had removed the glands in all operations of the nature under discussion except in one case in which the small growth removed had turned out to be one of the type in which there was not any tendency for small-celled infiltration to descend in columns or individually. The patient remained well, but he thought it was the exception that proved the rule. Referring to the case recorded by Mr. Butlin of successful treatment of epithelioma by radium, he (Mr. Bowley) was doubtful if the case was epitheliomatous.

Dr. BASHFORD pointed out how small growths on the tongue appeared much smaller on the surface than they were in the substance of the organ; as the growth descended it had a tendency to spread out in a fanlike form. He thought some attention should be paid to this possibility in addition to the significance of the amount of surface area affected and the degree of hardness of the growth. At his laboratory he and Dr. Murray had 43 different distinct carcinomas under observation and they would be unwilling to say that any one of the 43 was a duplicate of the other. He (Dr. Bashford) differed from Mr. Barker, because there were no means of saying how any particular carcinoma would behave.

Mr. BUTLIN said that only two points had been raised in the discussion to which reply was needed. First there was the difficulty of making a diagnosis between some of the early conditions of cancer and the conditions which might be mistaken for them. His drawings showed how very difficult this was. Hence, the safe course to pursue in all cases of doubt was to remove the disease, which could be done by a comparatively small operation, almost without danger. Secondly, there was the necessity of removal of the lymphatic glands in every case of cancer of the tongue. This was a matter which had occupied his attention incessantly during the last thirteen to fifteen years. He had come to the conclusion that it was his duty to advise patients with cancer of the tongue to have the corresponding glands removed. He quite agreed that there were cases in which it might not be necessary, and he admitted that some forms of epithelioma might be less dangerous to the glands than other forms; and the time might come when they might be able to distinguish between the more and the less dangerous forms. But at present they could not do so; and as he had shown that the glands might be fatally infected through the smallest and youngest cancer of the tongue, he felt sure that, for the present, the glands should be removed in every instance in which the patient could bear the operation. The discussion on this question that night reminded him of a somewhat similar discussion twenty-five years ago at the Harveian Society, when Sir Mitchell Banks came down from Liverpool to try and persuade them to remove the contents of the axilla in every case of cancer of the breast, whether the glands were enlarged or not. He (Mr. Butlin) was one of those who opposed his teaching on that matter, and pointed out that many cases could be collected in which the removal of the breast alone had sufficed to cure the patient, and that the glands had not become affected later, and that it was a very harsh measure to submit all patients to a large and dangerous operation (the mortality was then about 12 per cent.) which was only necessary in a certain proportion of the cases. All that was true, but Sir Mitchell Banks was right and he (Mr. Butlin) was wrong, and he ventured to say there was not any surgeon of distinction and repute in this or any other country who did not make a practice of removing the contents of the axilla in operations for cancer of the breast.

Dermoid Cyst of Mediastinum.

Mr. GODLEE showed a case of dermoid cyst of the mediastinum treated by operation and illustrated by a

pathological specimen. This was the continuation of a case presented to the Clinical Society before operation by Mr. G. E. O. Williams and Dr. Batty Shaw on October 27th, 1905 (reported in *Trans. Clin. Soc.*, 1906, xxxix, 210, describing the previous history, clinical signs, and symptoms). The patient was submitted to several operations in University College Hospital. In the first of them the lower part of the cyst was exposed by the removal of costal cartilages. The upper part was in such intimate relation with the large vessels at the root of the lung that its removal was impossible. Some portions of its inner wall and large quantities of hair were taken away. On subsequent occasions other portions of the skin lining the interior were cut away and cauterized. The result had been a considerable improvement in the general health and a diminution of the expectoration. But a large opening remained, in which the deep part of the cyst appeared, a forcible pulsation being transmitted to it by the action of the heart. There was a certain amount of discharge, consisting of mucus and sebaceous material, with a characteristic offensive smell. There had been several attacks of haemoptysis, in some of which a considerable amount of blood had been lost. Hardly any hairs were now produced. The pathological specimen shown was one presented to the museum of the Royal College of Surgeons by Mr. Thomas B. Monat, of the Royal Boscombe and West Hants Hospital. It was reported by him in the *BRITISH MEDICAL JOURNAL*, 1909, i, 90. It was under the care of Dr. Bottomley, and had been diagnosed as one of tuberculous glands. The cyst, which was on the left side of the chest, presented many features of resemblance to that of Mr. Godlee's case. The lower part was intimately associated with the pericardium, the upper was imbedded amongst the large vessels of the mediastinum. The importance of considering the specimen in connexion with the living case was that it was possible thus to appreciate the kind of difficulty likely to be encountered in any attempt at removal of these particular cysts, which were in all probability teratomas.

Gonorrhoeal Rheumatism.

Mr. GODLEE also showed a man with feet deformed by gonorrhoeal rheumatism.

Orycephaly.

Dr. H. MORLEY FLETCHER showed 4 cases of oxycephaly. They exhibited the characteristic abnormally-shaped cranium, exophthalmos due to imperfect formation of the orbits, impairment of vision, the result of partial or complete optic atrophy, and varying degrees of malformation of the superior maxilla. There was no obvious defect of intelligence in any of the cases shown.

Diffuse Periostitis of Tibias.

Mr. P. MAYNARD HEATH showed a case of diffuse periostitis of both tibias without other evidence of congenital syphilis, and a case of congenital syphilitic knee.

Congenital Splenomegaly.

Dr. F. PARKES WEBER showed a case of congenital splenomegaly with chronic acholuric jaundice in a boy, aged 14. There did not appear to be much evidence that the chronic acholuric jaundice was "haemolytic" in the case; at all events, the evidence that it was due to congenital fragility of red cells was insufficient. An interesting point was that the patient's mother said that all her children were born yellow, and remained yellow for three to six months after birth, but the jaundice was permanent only in the patient exhibited. Dr. Weber also showed a case of chronic swellings of the fingers in a woman, aged 20. The only thing of which she complained was a persistent swelling or hard oedema of all her fingers, more or less noticeable as long as she could remember. The case seemed to be allied to those of so-called "acrocyanosis."

Acromegaly.

Mr. R. HIGHAM COOPER showed a case of advanced acromegaly. The patient was a man aged 51, who stated that the enlargement of his extremities was first noticed in the great toes seventeen years ago. Several attempts to take skiagrams of the sella turcica had been made, but without success.

Elephantiasis Treated by Lymphangioplasty.

Mr. W. SAMPSON HANDLEY showed a case of elephantiasis treated by lymphangioplasty in a clerk, aged 46, who had never been abroad. The disease began in 1895 with swelling of the left testicle and pain in the left leg. The patient had now been back at work for some weeks, and there seemed to be every prospect that the result of the operation would be permanent.

Leprosy.

Dr. HERBERT P. HAWKINS showed a case of leprosy exhibiting trophic changes in the hands and feet, with anaesthesia. The patient was a girl, aged 19, who was born of English parents at Perambur, about three miles from Madras. About two miles from her home was a leper hospital.

Anaurotic Family Idiocy.

Dr. POYNTON showed a case of anaurotic family idiocy in a female, aged 9 months, who was brought to the hospital because she was unable to sit up; she had a dull and heavy expression, and was apparently almost blind. The particular points of interest were: The early age at which suspicion was aroused, the extremely well-marked changes in the fundi, the superficially healthy appearance of the infant, and that the diagnosis of rickets had been made, as in three other cases under observation in the last four years.

Splenectomy.

Mr. L. COLLEDGE (for Mr. W. E. FISHER) showed a married woman, aged 47 years, on whom splenectomy had been performed for splenic infarction.

Exhibit.

Dr. M. MACNAUGHTON-JONES, jun., demonstrated a simple appliance for obtaining and automatically maintaining any required pressure above or below that of the atmosphere within any closed cavity containing air.

SECTION OF SURGERY.

Tuesday, February 9th, 1909.

WARRINGTON HAWARD, F.R.C.S., President, in the Chair.

Lymphatics of the Colon.

Mr. J. F. DOBSON read a paper, prepared in association with Mr. J. KAY JAMIESON, on the lymphatics of the colon. Their observations were based on the examination of 23 specimens injected with a suspension of Prussian blue. A minute description of the arrangement of the lymphatic vessels and glands, with a classification into epi-colic, para-colic, intermediary, and main groups, was illustrated by numerous diagrams and pictures. The special interest of the investigation lay in relation to cancer of the colon. The comparative immunity from glandular metastasis and recurrence after removal, generally thought to be enjoyed by these growths, was not borne out by statistics, and the work of Clogg and others went to show that local and visceral recurrences were not uncommon. Disseminated cancer cells might lie dormant in the glands for considerable periods. The observations of the authors showed that dissemination might take place along the chain of glands that ran parallel to the long axis of the gut, and thence, following the line of the mesenteric vessels, towards the apex of a triangle of mesentery whose base extended for a considerable distance on either side of the actual growth. The practical outcome of this must be evident, but it was shown, with reference to actual cases, exactly what areas must be removed to secure complete extirpation of the affected tissues, with growths at various points in the course of the colon. In the course of their investigation of a case of cancer by serial sections of the mesenteric area involved, they were able to confirm the observation that glands apparently normal might be the seat of cancer cells, and that, on the other hand, glands might be enlarged owing to the absorption of products from the ulcerated surface and yet contain no cancer cells. They had reason to believe that infection was by embolism and not by permeation, and observed that communications existed between the lymphatic vessels and the veins. One important practical point was that the whole lymphatic area of the splenic flexure cannot be removed.

The Torus Palatinus.

Mr. RICKMAN J. GODLEE read a paper on the torus palatinus, and exhibited many casts, photographs, and specimens. The torus was a median ridge, boss, or vallum, sometimes with a median sulcus, occasionally found beneath the mucosa of the hard palate. Patients were now and then brought to surgeons with a small tumour in that situation, and it was important to know that such a swelling might be not abnormal. Mr. Godlee had come across such cases in his practice and was led to investigate the frequency of its occurrence. He examined some thousands of skulls in the Hunterian Museum and at Oxford; he obtained from dental surgeons, Mr. Mummery and Mr. Hern among others, several casts of the condition, and he was able to collect a considerable literature. The outcome of his research was to show that such a condition was not very uncommon, and that it had no little interest from the anthropological point of view, inasmuch as it appeared to be of much greater frequency amongst the primitive races.

Mr. BUTLIN mentioned a case he had had, with special reference to the fact that in the course of five or six years there appeared to be some slight increase in size, which might, however, be due to the soft parts over the bony boss. He considered it of interest that the daughter of his patient had also a "torus."

Professor KEITH thought it was undoubtedly a racial characteristic, and decidedly most marked in the primitive skulls. The Neanderthal skull had a marked heaping up of bone along several of the sutures, of the same character as that which formed the "torus." He was unable to assign any cause for such local hyperplasia.

Mr. TURNER said it had been regarded as a stigma of degeneration, but amongst 530 inmates of an asylum examined by him it was present in only two. He thought that some cases of swelling in this situation might be of the nature of hypertrophic exostoses similar to those found with pyorrhoea. He had examined a great many animals, and had found a torus in not a few; there were few among the higher apes, few among the carnivora; he had found it present in a porcupine and a manatee.

Mr. STANLEY MUMMERY believed that in some instances the swelling might be pathological and even become cancerous.

Mr. HERN made a few remarks about his specimens, and said the sister of one of his cases had also the "torus."

Mr. GODLEE, in reply, said he thought the torus was undoubtedly an anatomical peculiarity, and not a pathological condition.

SECTION OF MEDICINE.

Wednesday, February 10th, 1909.

T. H. GREEN, M.D., in the Chair.

Ulcerative Colitis.

THE adjourned discussion was opened by Sir PATRICK MANSON. He considered that ulcerative colitis was merely the name of a phase of a disease which hitherto had been described under the term "dysentery." The same virus, whatever it might be, might cause gangrene, ulceration, or catarrh of the colon. But dysentery was not itself a disease, only a symptom-complex. He divided dysenteries into bacterial, protozoal, and vermicular. Operation performed, as it would be in the tropics, by unaccustomed surgeons was not a hopeful method of treatment. The great majority of cases of dysentery imported into this country were amoebic dysentery, which was amenable to treatment by ipecacuanha. Dysentery with persistent pyrexia was probably either malarial or complicated with liver abscess.

Dr. CLAYE SHAW alluded especially to asylum dysentery. In his experience the disease in the asylum epidemics attacked earlier and to a far greater extent the insane patients with nerve degeneration, the healthy staff later and in slighter degree, thus arguing for the great importance of a nervous factor in the causation of some cases of intestinal ulceration.

Dr. SIDNEY PHILLIPS thought ulcerative colitis was much more common than formerly, and suggested that certain alterations in the food supply of the community might be an explanation. He referred to the frequency of severe pain in ulcerative colitis; also to the occurrence of

leucocytosis and the frequency of hiccough in his experience. In his cases no other bacteria than streptococci and *Bacillus coli* were found. He had found benefit in some of his cases from giving mercury, and from adrenalin in some of the haemorrhagic cases. He had seen improvement from surgical operation, but never immediate cure. It was to be remembered that sometimes the cases recovered spontaneously.

Mr. W. G. SPENCER mentioned a case in which great improvement took place after colotomy and irrigation, but in which any attempt to close the opening brought back the symptoms.

Dr. NORMAN DALTON mentioned a case of multiple papilloma of the colon which clumped Shiga's bacillus; he had lately met with a case of ulcerative colitis which clumped the typhoid bacillus and Flexner's bacillus, but not Shiga's bacillus. The important point seemed to be rather the virulence of the organism present than any specificity. He considered that cases had been saved by colotomy, and in his experience it had been possible to close the colotomy wound.

Mr. LOCKHART MUMFERY said that by the use of the sigmoidoscope the type of ulceration present could be made out. There were many different types, and he thought it was the cases with deep ulceration that did not get well under medical treatment. Of his series of 20 cases coming to operation there were only 5 that were fatal. Appendicectomy he thought the operation of choice; in his experience marked and rapid improvement followed. If it failed caecostomy could be done.

Dr. BERTRAND DAWSON alluded to the difficulty of gaining a clear idea of what was understood by ulcerative colitis. The two chief symptoms in the cases he had analysed were hectic fever and marked wasting. The typical cases conformed very closely to dysentery. Appendicectomy did much good in many cases, but return to ordinary life was often followed by relapse. He suggested as a possible cause of colitis the excretion of some toxin by the colon. If the real cause were above the ileo-caecal valve the frequent failure of operation would be explained. The use of *coli* vaccine had been followed by improvement in a few cases in his experience.

Mr. ZUM BUSCH described cases in some of which colotomy was done in the transverse colon, the bowel being completely divided and the distal end closed, with good results.

Sir WILLIAM ALLCHIN replied.

PATHOLOGICAL SECTION.

Tuesday, February 16th, 1909.

Mr. S. G. SHATTOCK, President, in the Chair.

A Statistical View of the Oponic Index.

Mr. M. GREENWOOD, Jun., read this paper. He said he thought it was clear enough that the value of oponic determinations had been disputed by experimental workers whose records appeared—at least to a statistical outlooker—to entitle them to some more conclusive answer than the facile charge of imperfect technique. The pivot upon which the whole question turned was evidently the degree of credence to be attached to mean phagocytic power as determined from a small number of cells. It was necessary to examine with some attention the possible sources of error or uncertainty which may be shown to exist. It was not difficult to see that the errors involved fell into two groups. They had first the errors of technique, using the term in its widest sense, and secondly the error dependent on the fact that they measured not all the cells but a sample of them. One took the data furnished by an experienced observer, analysed them, and obtained a measure of uncertainty—that is, found that two samples differing one from another by not more than an assigned amount could not with certainty be referred to separate classes or "populations." How much of this uncertainty depended on the worker's incomplete technical skill and how much on inherent biological variability it might not be possible to define. He must be understood to speak only of the error attaching to the method as practised by the best workers at the present time, and he would describe as briefly as he could the principles upon which the study of this error seems to be possible. Dr. White

and himself had undertaken a tolerably extensive study of the variation observed in the enumerations of phagocytic cells made for the purposes of the oponic index with respect to the tubercle bacillus. Their material consisted of fifteen counts of cells made by Dr. Alexander Fleming, Dr. T. P. Strangeways, and his co-workers Miss Fitzgerald and Dr. Whiteman. The smallest count in the series was of 400 cells, the largest one of 2,000. The majority included 1,000 cells. They employed the usual processes of statistical analysis, and found that while not one of these counts could by any possibility be regarded as "normal," all with one unimportant exception, were extraordinarily good examples of variation described by skew curves. The types discovered were those known as Pearson's first and fifth types. The charts exhibited were examples from their series; all told the same story, so that it was unnecessary to trouble them with a multitude of diagrams. On the analytical features of these curves he did not propose to dwell. Any one interested in the matter would find a detailed examination of them in a recent memoir by Dr. White and himself, published in *Biometrika* (1909, vi, Part 4). Some general features of the results were, however, worth immediate notice. In the first place, it was apparent that the distributions were highly asymmetrical, or, in technical language, exhibited "skewness" of a high order. That, of course, was an experimental proof that the Laplace-Gaussian postulates with reference to the causes of variation were, taken as a whole, inapplicable to these examples of phagocytosis. It was an interesting matter of speculation, at any rate, to inquire how this variation might conceivably have arisen. Sir Almoth Wright had offered the following solution: In any mixture of serum, corpuscles, and bacillary emulsion, the actual number of bacilli present might be large enough to give each phagocyte more bacilli than were ever ingested even by the most highly charged cell in the count. But, since the mixture of the respective constituents was not perfect, all phagocytes had not the same chance of ingesting bacilli; some cells had numerous bacilli within reach, as it were; others were far away from the well-spread board. If the hypothesis were true, the Gaussian postulate that no one cause-group contributed much to the total variation did not hold for phagocytic counts. Therefore, a skew distribution might be expected, and would, not improbably, take the form actually observed. Beyond that Mr. Major Greenwood said he must not go. Accordingly, while such a hypothesis was consistent with their results, it was to be remembered that a multitude of other hypotheses, including one of a true biological variability of the cells, would accord equally well with the ascertained facts. Thus the observation that all their frequency curves had a negative start—allowing for a bacillary content of less than zero per cell—might by some be thought to warrant a belief that certain phagocytes were, if the expression be permissible, negatively chemotactic. It was further to be observed that even if Sir Almoth Wright's hypothesis found entire acceptance, the necessity of testing the method on the basis of skew frequencies remained. Let them conceive of a diagram as representing the whole "population" of cells involved in any one case. Then let them remember that in practice one took a small handful of fifty or a hundred cells blindfold from this "population." The most superficial consideration of the diagram led at once to the following conclusions: (1) They were not equally likely to obtain random samples, each of which differed by the same quantity from the mean of the whole "population," one in excess, the other in defect. In other words, samples were liable to biased error. (2) The range beyond the mean was greater than the range up to the mean. Therefore, great positive deviations might conceivably occur in random sampling while correspondingly great negative deviations were excluded. This, of course, only applied to extreme deviations. (3) Owing to the marked skewness of the curve the mean was not a good descriptive constant; the mode (the most frequently occurring as distinct from the mean value) was more reliable. The truth of propositions (1) and (2) would be further illustrated in the sequel: (3) was, he thought, of some importance. The whole object of employing a mean value was to have expressed by a single constant some of the main features of a distribution. In any symmetrical frequency, such as the "normal" curve, the mean coincided

with the mode and was evidently the most useful single constant they could obtain. When, however, there was a marked skewness, as in their phagocytic counts, since the mean and mode were far apart, knowledge of the mean only might lead them to form a very incomplete idea as to the general features of the count. The mode, on the other hand, was relatively better for summarizing purposes, although, of course, no one constant would render an adequate account of any frequency-system. For these practical reasons and certain theoretical ones which he need not discuss, he suggested that it was advisable to replace the mean by the mode for testing indices. Unfortunately, the true mode could only be found by a relatively long arithmetical process; still, even a value determined by inspection or the roughest graphical consideration was not improbably better than the arithmetic mean value. The largest count in their series was one by Dr. Strangeways and his colleagues of 2,000 cells, a count made up of eighty samples of twenty-five. Taking the eighty means as separate observations, they analysed the resultant frequency distribution and obtained the curve exhibited in the diagram. It was a well-marked example of Type 1, sensibly skew and an excellent fit. While admitting that the number of means upon which the result was based was comparatively small, the excellence of the fit led the speaker to think that it afforded a provisional solution of the problem as far as samples of twenty-five were concerned. As before, let them imagine that this curve represented the whole "population" of means. Then the chance that drawing a sample from this population would give them a result not differing from the "population" mean by more than an assigned amount was merely a question of areas. Thus the chance in favour of getting a sample mean of 1.353 or less was the ratio of the area from the start bounded by the ordinate 1.353 to the rest of the area. The odds against this were 5.68 to 1. In terms of the "real" mean this deviation corresponded to an index of 0.8. In this way they saw that the odds against random sampling being responsible for indices of 0.9, 1.1, 1.3 were respectively 1.88 to 1, 3.6 to 1, 12.46 to 1. This amounted to saying that even so extreme a deviation as 1.3 might be reasonably expected to appear rather less often than once in thirteen times merely as a result of random sampling and without any coincident physiological change in the "population" whatever. In other words, no definite importance could be assigned to variations within the limits of 0.8 and 1.3 at least. He was aware that workers seldom relied on samples of twenty-five cells, although very far-reaching conclusions had in the past been based on counts of this size. How far the limits of probable variation would be narrowed by a consideration of samples of 50 or 100 was not certain. That they would be narrowed to some extent, but not it might be very much, was probable. Dr. White and he had, they thought, succeeded in showing that:

- (1) Phagocytic distributions were markedly asymmetrical.
- (2) This asymmetry, although reduced, was not removed by emulsions of (from the experimental standpoint) maximal thickness.
- (3) The mode of a phagocytic distribution was a more reliable constant than the mean.
- (4) A corollary of (1) positive and negative deviations would not occur in random sampling equally often. Further, they had not proved, but rendered somewhat probable, that samples of twenty-five were unreliable, at least within the limits of 0.8 and 1.3.

OTOLOGICAL SECTION.

A MEETING was held on February 6th. Dr. PETER MACBRIDE, President, in the chair. The PRESIDENT read notes of a case of *Dermoid of the mastoid region*. The chief point brought out was its extreme rarity. Dr. DAN MCKENZIE exhibited a *Mastoid pillow*, the peculiarity of which was an opening in the centre sufficiently spacious to receive the ear and mastoid region without exercising any pressure on the tender parts; the object being to allow the patient to lie on the side operated on in order to permit of more free drainage. Mr. ARTHUR CHEATLE showed a case of *Chronic middle-ear suppuration with caries of the anterior mental wall and zygoma*. The probable actual cause was traumatic, the result of the patient's pushing a piece of wood into the ear. In Mr. Cheatle's opinion the caries of the bone was entirely separate from the chronic middle ear suppuration, which

had existed from boyhood. He thought the local wound caused by pushing in of the wood had become infected by the middle-ear discharge and so caused osteitis. Dr. KELSON read notes of a case of a girl who was exhibited at the previous meeting on account of having both *External auditory meatuses filled with white deposit*. At that meeting the provisional diagnosis of diphtheria was made. Cultures, however, showed the presence of *Staphylococcus aureus*, and a cure was obtained by the frequent instillation of glycerine of carbolic acid. Mr. SYDNEY SCOTT demonstrated a series of lantern slides showing *Hair cells in the organ of Corti (human)*. Mr. C. E. WEST showed cases and specimens illustrating *Malignant disease of the external auditory canal and middle ear*. He mentioned that he had seen 7 such cases in two years, and suggested that malignant disease of the ear was more frequent than was generally supposed, and that the condition, perhaps, had been frequently missed owing to lack of careful examination. Mr. HUNTER TOD read notes of a case of *Chronic osteo-mycetitis of the skull, the result of mastoid disease (with specimen of calvarium)*. The condition occurred in a woman who had suffered from purulent discharge for two years and who was operated on on account of a large abscess of the mastoid process. At the time of operation a large area of bone above and behind the mastoid process was found to be necrosed. The skull gradually became affected throughout its entirety until eventually, after nine months, the patient died as the result of meningitis. This case, in the opinion of the Section, was unique, although similar cases had been described as a result of infection through the frontal sinuses.

MEDICAL SOCIETY OF LONDON.

Monday, February 15th, 1909.

JOHN LANGTON, F.R.C.S., in the Chair.

Functional Disorders of the Stomach.

Dr. SIDNEY MARTIN, in his second Lettsomian lecture, said the motor power of the stomach varied very considerably in disease, and the deficiency was towards weakening the motor power both in functional and organic disease, that was, it was towards dilatation of the organ. Dilatation occurred as a result of gastric irritation, of gastric insufficiency, and of organic disease, more particularly of pyloric stenosis and other forms of obstructive disease which hindered the expulsion of the stomach contents into the duodenum. It played a great part in stomach disease, being in so many cases the main sign observed that the distinction between functional dilatation and that due to organic disease was of very great importance. In hyperchlorhydria the stomach might show no loss of motor power for a long period, months or even years; but in some cases signs of dilatation occurred and the stomach might become greatly dilated. The dilatation might be diagnosed by presence of the stomach tumour, by a succussion splash in the stomach, and by the determination of the stomach area by means of auscultatory percussion. Other means of diagnosis were inflation of the organ by air or by making the patient drink 30 grains of sodium bicarbonate in 4 or 5 oz. of water, and the same quantity of tartaric acid in water. The normal stomach held about 35 oz. of water (although it varied very considerably in size), and the determination of the amount of liquid which the stomach could contain was sometimes useful as an additional method of diagnosis. The amount contained might be estimated by seeing how much could be tolerated in the stomach without distress, and how much could be siphoned off afterwards. Signs of slight dilatation occurred commonly in functional disease, more particularly in cases of gastric insufficiency and of nervous disorder. The term which some would apply to that condition was not dilatation, but myasthenia. He did not think it was necessary to use that term as long as one considered the important point that in many such cases signs of dilatation occurred only after a meal, and might disappear in four or five hours. Dilatation might thus be temporary. As the condition progressed, it tended, however, to become permanent. A point that must be considered was whether great dilatation of the stomach was ever the result of functional disease. There was no doubt that this did occur. Such great dilatation was unmistakable, inasmuch as the stomach formed a flabby bag in the abdomen which was readily palpated

and the outlines of which could be recognized with a fair amount of accuracy. The importance of the recognition that functional disease might cause great dilatation of the stomach was evident from the fact that the operation of gastro-enterostomy might be suggested for such a condition, which by other means might be relieved. Gastropnoxis was a condition which required a separate discussion. It usually occurred in women who had lax abdominal walls, and not infrequently in those who had had many children. It might, however, occur in single women. In it the stomach was greatly dilated and sank in the abdomen, the lower border being nearly on a level with the pubes. In such a case there was a bulging of the lower part of the abdomen which was most obvious when the patient stood up, and frequently on standing up there was a dragging pain in the abdomen which was removed when lying down. Gastropnoxis was in many cases associated with a previous prolonged period of indigestion of food, and was directly associated with pain, vomiting, and wasting. It was sometimes associated with enteropnoxis and with movable kidneys. In one such case occurring in a multipara, aged 42, indigestion had lasted eight years. There were well-marked signs of gastropnoxis. The secretory activity of the stomach was as follows: the total hydrochloric acid secreted was 0.23, digestive activity 72 per cent., and no organic acids were present. There, in spite of the prolonged symptoms and the dilatation of the organ, the secretory activity of the stomach was normal. The patient lost all the symptoms when the stomach was stitched up. In another case, also that of a multipara, there were similar signs of gastropnoxis; the secretory activity was 0.12 hydrochloric acid. It was evidently of great importance to have a clear idea as to what were the causes which produced irritation of the stomach, not only from the point of view of diagnosis, but also, what was more important, from the point of view of treatment. In the first place must be put imperfect mastication which might be due either to the bad habit of bolting food, or to the deficiency in number and soundness of the teeth. In the next place food, either in too great quantity, too rich, too highly spiced, or too indigestible, was a frequent cause of irritation of the stomach. That was a cause which frequently acted for years, and if combined with sedentary habits led to grave defects of nutrition and serious damage to the digestive organs. Meals taken at irregular times and exercise or work soon after a meal were also a source of stomach irritation. The deficiency of daily exercise with the causes already mentioned, and rush and over-excitement of life, with perhaps periods of stress and worry, might lead to grave gastric disorder. Briefly, it might be stated that it was proper regulations for remedying the defects enumerated which resulted in successful treatment of such cases. The stomach was also readily affected by nervous influences, chiefly emotional, leading to secretory and motor disturbances. One other cause of irritation of the stomach, and one of the first importance when present, was a chronic intoxication from bacterial sources which resulted from pyorrhoea alveolaris, from chronic tonsillitis and discharges from disease of the nasal passages and from the antra, which when swallowed led to chronic poisoning of the body. In some cases the removal of those sources of intoxication led to a recovery of the individual. In other cases chronic intoxication resulted from drain emanations in the house. In a certain number of cases of functional disorder intestinal intoxication resulted partly from putrefactive processes of the faeces and partly from infection of the pancreas through the pancreatic duct or from the appendix. Dr. Martin concluded by considering in detail advanced cases of functional disorder and indigestion of nervous origin.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Friday, January 29th, 1909.

R. D. PUREFOX, M.D., in the Chair.

Modified Instruments.

Dr. ASHE demonstrated a new principle for application to Bozeman's catheter and Braun's hollow sound by means of which every part of the uterus could be dealt with with

out fear of undue pressure. The instrument which he exhibited allowed all the fluid to come back, and with it the uterus could be flushed out. It was simple and cheap, and could be absolutely sterilized.

The CHAIRMAN considered that the instrument had a wide range of utility.

Adeno-carcinoma of Vulva.

Dr. SOLOMONS exhibited specimens of this condition. Adeno-carcinoma of the vulva was very rare. He was able to show the specimens by the kind permission of Dr. Tweedy, the Master of the Rotunda Hospital.

M. W., aged 33, married eight years, 4-para, was admitted in November, 1908, to the Rotunda Hospital. She had noticed a lump in the vulva two weeks before admission, and this ruptured just before she entered the hospital. Pruritus was absent. Patient was blanched from loss of blood. On examination it was found that there was a large stinking mass protruding from the vulva, which seemed to spring from inside the right labium, just at Bartholin's gland. The tumour was evidently a haematoma. On its removal an excavated sloughing sore came into view, which had all the appearance of acute phagedaena. A microscopic examination showed nothing save blood clot. The cavity was plugged with iodoform gauze. Thinking that perhaps the affection was syphilitic, the patient was given a mixture of hydrarg. perchor. and potassium iodide. Insufflation with calomel was also used. Two weeks later, as there were no signs of improvement, the excavated sore was opened up, scraped, curetted, and thoroughly swabbed out with iodized phenol. In spite of this treatment, combined with keeping the wound plugged with peroxide of hydrogen, alternating with formalin 1 in 5, together with the antisyphilitic treatment, the phagedaenic sore spread with alarming rapidity, and it became evident that a condition of malignancy probably existed; this, despite the fact that no glandular enlargement existed anywhere and the negative microscopic findings. Therefore, under an anaesthetic, the parts were explored, and the curette, knife, scissors, cautery and nitric acid were freely used in an endeavour to stay the disease, whilst large portions of the tissue that had not sloughed were removed for microscopic examination. Although the infection spread over to the other side, yet the urethra seemed in no way implicated, and lay in the midst of the disease as an isolated tube.

Dr. ROWLETTE reported that the case was one of adeno-carcinoma of the vulva. This diagnosis was only arrived at after he had cut a great many sections. There were no apparent primary growths in any part of the body, and the only possible original seat of the disease seemed to be in Bartholin's gland.

Ruptured Extrauterine Pregnancy.

Dr. FREELAND exhibited specimens. They were taken from a patient, 35 years old, who had been married fifteen years and had had four children and four abortions. She had come to him two weeks before complaining of haemorrhage, and menstruation overdue two weeks. On examination she was found to have retroverted uterus and a small tubal mass in the left side. He thought she had a tubal pregnancy. She would not remain in hospital; she had considerable pain when she went home. She returned the next day, and the following Tuesday he operated. On opening the abdomen he found the pelvis full of blood. The fetus had escaped into the abdomen, and was attached by the cord to the rest of the ovum in the tube. The ovary was left in position, and she had done very well.

Remarks were made by the CHAIRMAN and Dr. HOLMES.

Double Pyosalpinx.

Dr. FITZGIBBON exhibited specimens. They were from a patient aged 31. She had been married seven years, and had had one pregnancy, which ended at term, five years before the operation in August last. She had been under observation eighteen months, and during that time very little change was seen in the pelvic condition. The uterus was normal in size and hard. On the right side there was a hard mass pressing down on the right fornix, and on the left side they could make out a tube thickened but not embedded. Her periods were normal, and she was very little troubled until the last six weeks, when severe pain came on. The abdomen when opened seemed tolerably normal until he attempted to pull up the intestines, when nothing would move, and he found the whole of Douglas's pouch filled with adherent small intestines. He got the whole of the tumour out without tying any vessels, as they had been obliterated. He closed the stump of the cervix with two interrupted sutures and packed the pelvis with

gauze. Two days after the operation the pulse went up to 110, though the temperature neither then nor subsequently went above 99°. He withdrew the gauze and put in a long drainage tube. On the third day the pulse rose gradually to 160; the following night it fell to 140. He then put in a shorter tube. She continued to improve, but next morning he found a smell of urine. He replaced the tube with one of rubber, and concluded that the drainage tube had sloughed through the bladder. He kept the tube in until he got a diminution in the amount of pus, although some still came away in the urine. The patient made a good recovery. The case showed the danger of hard drainage tubes put through the abdominal wall into the pelvis, and also showed how pyosalpinx, which was obviously chronic for eighteen months, could still set up an infection of the pelvis, although it was stated that if left for twelve months the pus would become sterile.

The case was discussed by Drs. HOLMES, JELLETT, and GIBSON, and Professor ALFRED SMITH and the CHAIRMAN.

Radical Cure of Backward Displacements of the Uterus.

Dr. JELLETT read a communication on this subject. He began by discussing the present attitude of gynaecologists towards the radical cure of backward displacements of the uterus. He considered that in all cases in which the symptoms called for relief a radical operation should be performed in preference to the prolonged use of a pessary. As exceptions to this rule he mentioned puerperal displacements, as they could usually be cured by the temporary use of a pessary, and cases in which the circumstances or general health of the patient made operation inadvisable. He showed that, if a patient had to be curreted, the performance of a radical operation prolonged her stay in hospital only by a week. He divided the different radical operations into three groups: (1) Cases in which a major operation had been performed, and in which the peritoneal cavity had been opened. For these cases he always concluded the major operation by performing a ventral suspension. (2) Cases in which the displacement was complicated by adnexal disease. In these cases he advised the opening of the abdomen followed by ventral suspension. (3) Cases of uncomplicated backward displacement. In these cases he unhesitatingly advised Alexander's operation on account of its safety and its after-results. He then discussed Alexander's operation, and referred to the statements of Drs. Herman and Galabin, who considered it an essentially dangerous operation. In opposition to this he quoted statistics of 385 cases, practically all of which were successful, and amongst which there was a single death from croupous pneumonia, and unconnected with the operation. His own statistics were as follows:

Forty-four cases were operated on. In 39 the usual double incisions were made, and in 5 a single incision. There were thus eighty-three separate incisions, and every one of these healed by primary union. One incision subsequently suppurated, owing to the fact that the subcuticular suture broke during removal and was left behind. One patient died, but her death, which was from double croupous pneumonia coming on about a week after the operation, had nothing to say to it. In one case the uterus subsequently fell back, and in this case only one ligament had been shortened. The other was left, as it was difficult to find, and as the operation had been already prolonged by the preliminary steps of curreting, trachelorrhaphy, and sigmoidectomy. In this case the uterus was in a normal position when the patient was seen six months later, but it had fallen back when seen two years later. Two patients at least were subsequently delivered, and after delivery the uterus remained in a normal position.

Dr. Jellett then stated in detail the reasons he considered Alexander's operation the operation of choice in cases of uncomplicated backward displacement of the uterus.

Remarks were made by the CHAIRMAN, Professor ALFRED SMITH, Dr. ASHE, Dr. HOLMES, Dr. GIBSON, Dr. FITZGIBSON, Dr. MATSON, and Mr. L. G. GUNN.

Dr. JELLETT, in reply, said the difference between the treatment which he advocated and the use of the pessary was a week in hospital, and he thought that was less serious than two or three years' pessary treatment, even if in some cases the pessary succeeded. Kelly's operation was not an ideal one, but it had the advantage of taking very little time to do when the abdomen was already open. So far from Alexander's operation causing a hernia, it would probably cure any inclination to hernia, as the walls

of the inguinal canal were sutured and a patulous external ring was closed. Obliquity of the uterus was not, he thought, a matter of importance. In three or four cases in which he only shortened one round ligament he had in a month or so found the uterus in the middle line. The great majority of cases were those in which the uterus had fallen back after childbirth, and in these there was no necessity to look for causes of sterility; but if there was any doubt as to the condition of the adnexa, he agreed with Dr. Holmes in opening the abdomen. In one of his cases a patient became pregnant afterwards, and had great pain from pulling on the external abdominal ring as the uterus developed. The uterus was also very large, and there was hydramnios. He feared during pregnancy that the operation was in some way responsible for this, but eventually the woman was delivered of a stillborn syphilitic infant. He thought that a similar cause probably accounted for the repeated abortions in the case recorded by Dr. Purefoy.

LIVERPOOL MEDICAL INSTITUTION.—The third pathological meeting of the session was held on February 4th; the PRESIDENT (Mr. T. H. Bickerton) in the chair. Mr. NEWBOLT showed: (1) *A Lipoma removed from the ischio-rectal fossa of a lady.* The symptoms were those of a chronic ischio-rectal abscess. (2) *A Calcified fibroma of the thigh which had been present for fourteen years.* (3) *Recurrent myxoma of the thigh.* (4) *Hairball removed from a girl's stomach.* A bismuth x ray showed the mass projected through the pylorus. Dr. HARCOURT showed: (1) *Horny growth from the lower eyelid.* (2) Two cases of *Malignant disease of the ear.* (3) *Cyst of the eye following a kick some years before.* The resulting blindness was attributed to detachment of the retina. Dr. GROSSMANN considered this case to be one of embryonal lens, due to the growth of some displaced portion of ectoblast. Dr. LEITH MURRAY showed: (1) *A section of a Supravrenal rest found in an inguinal hernial sac.* (2) *Sarcoma of omentum.* (3) *Eggshell fibroid of the uterus.* Dr. TINNE showed a specimen of *Trachina viperæ.* He remarked that the venom fangs of snakes in that no venom had ever been demonstrated. The local effects of being struck were vaso-constriction, followed rapidly by a hard white oedema. Dr. LLOYD ROBERTS showed a *Lung with an azygos lobe,* and read a note on malformations of the lung. Mr. THELWALL THOMAS and Dr. MURRAY BLIGH showed: (1) *A Gall bladder with calculus blocking the cystic duct removed from a woman aged 54 years.* (2) *Thyroid adenoma with a shrivelled calcified cyst in its centre; the cyst had been tapped eight years previously.* (3) *Exophthalmic goitre removed from a girl aged 18 years.* Symptoms had been present for twelve months. Marked improvement followed operation. Sections showed great proliferation of the acinous epithelium with little colloid material. Dr. ERNEST GLYNN showed: (1) *A Heart with large vegetations on the aortic valves containing pneumococci.* The man had enjoyed good health until attacked with lobar pneumonia seventeen days before death. (2) *A case of Bronchiectasis,* with abscesses in the lower lobe of the right lung, due to impaction of a clove in the bronchus, which must have been present for several weeks. Sir ROBERT BOYCE read a note on *Actinomycosis as a source of infection for man.* He had examined a considerable number of cases of this disease in pigs and cattle, and noted the frequency with which the udder of the cow had been affected. He suggested the possibility of milk being affected from the diseased udder, and gave this as an additional reason for the sterilization of milk before consumption. Dr. T. R. GLYNN referred to a case of actinomycosis which had commenced in the lung, and later gave rise to nodules in the legs. Inquiry failed to elicit the possible source of infection.

In the New York Supreme Court a decree was recently granted to a woman annulling her marriage with a man on the ground that at the time of the marriage he was suffering from tuberculosis, and was, therefore, incompetent to contract a marriage. The husband, although he had put in an answer to her complaint, did not appear to defend the action when the case was called for trial.

Reviews.

THE PROLONGATION OF LIFE.

No subject can be of greater interest to the human race than that of the prolongation of healthy life. Many writers, well qualified to speak with authority, have put forth their views from time to time, and the admirable lecture, *On Means for the Prolongation of Life*, delivered some five years ago before the Royal College of Physicians of London by Sir HERMANN WEBER,¹ may be said to have summarized the main conclusions upon which all are more or less in agreement. A third and enlarged edition of this lecture has recently been issued in which the various aspects of the subject are arranged in order convenient for reference by means of a comprehensive index, to which is appended a full bibliography.

Foremost among the conditions conducive to health stands the habit of regular exercise. The truth of the poet's line, "the Wise for Health on Exercise depend," was never more needful to be borne in mind than at the present time, when cheap, easy, and rapid means of conveyance are always at hand to tempt the middle-aged town dweller to ride when he ought to walk, and thus to allow his circulation to stagnate, his tissues to get clogged with effete products, and his whole organism to grow old before its time. The rush of modern city life too often leads to the notion that time spent on daily exercise is time wasted, but to those who are not blinded by the engagements of the moment and can look at the larger view of the question, the prospect held out by Sir Hermann Weber will demonstrate the wisdom of maintaining a due proportion between work and exercise under most conditions of everyday life.

Next in importance to exercise comes the question of diet. Popular tradition has long since established the notion that certain kinds of meat are more digestible and less "gouty" than others, and a section on foods, which appears for the first time in this edition, will aid in the extinction of some time honoured fallacies on these points, enabling the reader to gather from a few words the sum of actual knowledge on the subject.

Every man or woman who has lived for fifty years will have formed an opinion as to their personal requirements in the matter of food, but few of them would admit that they had arrived at a perfect diet and most would be willing to profit by the experience of those who have attained the goal of a healthy old age. With respect to drink, old customs are rapidly undergoing change, especially among the elderly, and the influence of moderation on longevity is becoming universally recognized. But the term "moderation" admits of wide interpretation and is sometimes used to cover an injurious amount of moderate drinking whereby the processes of degeneration are hastened and the attainment of long life is prevented. The critical period of life, during which the seeds of premature degeneration are most frequently sown, is that of early middle age. Between the years of 35 and 45, when the full vigour of manhood is most felt, the unrestricted indulgence in more food and alcohol than is needed with every meal must be attended by insidious changes in vital organs which do not show themselves until serious mischief has been done. The free liver who reaches the full term of life has generally combined his enjoyment of the good things of the table with habits of active exercise in some form; but the deaths of many men of fine physique before the age of 60 can often be clearly traced to the indulgences of previous decades. While he may never be the "worse for liquor" in a legal sense, he may be daily the worse for liquor in a physiological sense, and must pay the penalty by the shortening of his life.

Many elements combine to produce healthy longevity, and the part played by the nervous system has always to be borne in mind. Anything which may tend to depress the vigour of the nervous organization must react primarily upon nutrition, and the author cites many instances to show how physical vigour may be regained by mental activity after it has become stagnant from mental inaction. Mental, no less than physical, exercise

is an essential factor in the maintenance of health as life advances.

Sir Hermann Weber's book teems with wisdom, scientific observation, and common sense, and presents, in a form which is at once interesting and convincing, a true guide to the attainment of that which every one in his heart desires.

CARDIAC AND VASCULAR DISEASES.

FOLLOWING upon the first series of Professor VON NEUSSER'S *Clinical Treatises on the Symptomatology and Diagnosis of Disorders of Respiration and Circulation*, a second volume is now before us dealing with the subjects of *Bradycardia and Tachycardia*.² The translator is again Dr. Andrew MacFarlane, of Albany, U.S.A., and the value of the small but very comprehensive work is greatly enhanced by the addition, in an appendix, of a careful summary by Dr. Howell, of Baltimore, of the present state of knowledge with regard to the cause of the heart beat, and the steps by which it has been arrived at. A very complete bibliography of Adams-Stokes disease and of tachycardia also adds considerably to the practical value of the book. The phenomena of bradycardia and tachycardia, in spite of the efforts of physicians and experimental physiologists, are still open to controversy, and in this little work will be found a clear statement of the facts and theories which have up to the present time been observed or recorded. Bradycardia is first considered, and the three main theories of its production are duly weighed. Impairment of excitability, diminished conductivity, and enfeebled contractility on the part of the cardiac muscle, have each in turn held the field in discussions upon this point, and there can be but little doubt that they may each and all, together or separately, play a part where inflammatory or degenerative processes are at work. It is clear that the author believes that the Adams-Stokes syndrome may possibly be due to many causes. The chief stress is laid upon the epileptiform seizures rather than upon the cardiac lesion, which has in some cases been proved to be absent. The important difference between temporary and persistent bradycardia is rightly insisted upon, the latter condition being far more serious as regards prognosis. Tachycardia, in association with febrile disease, with drug intoxication and with various forms of heart disease, is fully considered, and its prognostic significance pointed out. The curious phenomena of paroxysmal tachycardia as opposed to symptomatic tachycardia are carefully described and discussed. The whole treatise may be cordially recommended to the notice of all workers in these difficult subjects, not only as affording a clear indication of the present position of knowledge, but as suggesting the lines upon which further investigation may travel in order to reach a clearer conception of the causes and curability of these peculiar conditions.

In a short monograph on *The Heart and Sudden Death*, Dr. THEODORE FISHER³ has brought together some papers contributed by him to a contemporary journal with the object of clearing up certain misconceptions which he believes to be prevalent. His estimate of the average intelligence of the present-day practitioners and morbid anatomists would appear to be low, if we may judge from the points of pathology which he deems it necessary to emphasize. The occurrence of sudden death both in unsuspected and in recognized heart disease is sufficiently frequent to render some of his comments superfluous. Fibroid degeneration of the cardiac muscle is, from the writer's point of view, one of the most important factors in the production of sudden death. Fatty infiltration, on the other hand, he relegates to a much less prominent position, and he does not regard the presence of fat in the interstitial structures within the heart wall as evidence of cardiac weakness. The view that the fatty heart is a common cause of death under an anaesthetic is held to be a myth, although fatty changes may be found

¹ *On Means for the Prolongation of Life*. By Sir H. Weber, M.D., F.R.C.P. Third edition. London: J. Bale, Sons and Danielsson. 1908. Demy 8vo, pp. 222. 4s. 6d.

² *Disorders of Respiration and Circulation*. By E. von Neusser, M.D., of Vienna. Part II. *Bradycardia and Tachycardia*, with bibliography. Authorized English translation by Andrew MacFarlane, M.D., Albany, U.S.A. New York: E. B. Treat and Co. 1903. (Demy 8vo, pp. 150. 81.25.)

³ *The Heart and Sudden Death*. By Theodore Fisher, M.D., F.R.C.L., Assistant Physician to the East London Hospital for Children. London: The Scientific Press, Limited, 1908. (Cr. 8vo, pp. 54. 2s.)

in such cases in association with fibrosis. He maintains that rheumatic endocarditis produces more uniform lesions than the endocarditis arising from other septic causes, and that these latter are more prone to cause irregular puckering of tissue and consequent obstruction of coronary vessels, leading to sudden death. Cardiac pathology presents so many puzzles to the clinician that the experience of those who have had especial opportunities of study is always interesting, if not always convincing; and we can commend Dr. Fisher's little monograph as well worthy of perusal, containing, as it does, a clearly expressed account of the writer's views on a subject to which he has devoted much attention.

The value of percussion as a means of determining the apparent size of the heart, although universally recognized, has, nevertheless, been the subject of much discussion at various times. In a recent monograph by Dr. ARAVENTINUS of Athens—*Die Perkussion in der Bestimmung der Herzgrößen*—the different views of observers in many schools have been brought together and examined very minutely by the light of his personal investigations and by the revelations of the Roentgen rays. No less than 274 references are given to the works of previous writers between the years 1761 and 1907, forming a very interesting historical summary of the views of competent observers, but showing very clearly that the personal element plays a considerable part in the conclusions at which they severally arrived. Roentgen-ray examination has greatly aided percussion, but it must still be confessed that their combined use, even in the most skilled hands, cannot always attain to accuracy. The writer of the monograph sums up with great care the lessons which may be learnt from the exhaustive study that he has made, but it is somewhat disappointing to note that these do not vary in any important point from the teachings of our own accepted textbooks.

Arterio-sclerosis is a fertile subject for investigation and discussion, and much has been done of late years to advance knowledge by both processes. Dr. L. M. WARFIELD, of St. Louis, Missouri, has brought together, in a compact little volume,² a very readable account of modern views on the subject, and makes many suggestive observations, which deserve further attention. Writing from exclusively American experience, he is of opinion that the rush and worry of modern business life is having a damaging effect upon the blood vessels of the present generation, and that diseases arising therefrom are more frequent than they used to be. Arterio-sclerosis would appear to be becoming somewhat of a catch-word amongst that section of the public which delights to talk about its diseases, and there is obvious danger that the supposed disease may be made the scapegoat for serious conditions arising from other causes. The author gives a good account of the physiology of the circulation, and shows how compensation for defect in one part may be effected in another, so that even an advanced condition of vessel change may not be indicated by definite symptoms. He also discusses the effects of adrenalin, and maintains that its abuse is liable to lead to degenerative changes in the muscular walls of the smallest arterioles. He directs particular attention to the liability of abdominal vessels to sclerosis, and considers that the vessels of young children after infectious disease are prone to sclerotic change. Incidentally he mentions the special liability of the coloured races to vascular degeneration. His views on prognosis and treatment do not differ materially from those generally accepted. The book constitutes a pleasant *causerie* on the whole subject, and as such may be read with advantage, but it makes no pretence to the precision and accuracy of a textbook.

AN INDEX AND A DICTIONARY.

BUT little more than twelve months have elapsed since we published a review of the first edition of the *Index of*

Treatment,³ by Dr. HUTCHISON and Mr. STANSFIELD COLLIER, and we have already to record the appearance of a fourth edition, fully revised and clad in a somewhat more imposing dress, but only enlarged to the extent of some thirty-five pages. Our commendation of the work as a really useful and practical aid to the busy practitioner has evidently been fully endorsed by a very large number of the fraternity. Every year brings with it fresh ideas of treatment founded on closer investigation of physiological and pathological processes, and there is always a tendency to run away with any new and attractive notion directly it has been brought forward, with the common result that it falls into disrepute owing to misguided application. A textbook of treatment, kept well up to the level of modern knowledge, can do much to prevent this by holding an even balance between scepticism on the one hand and over-enthusiasm on the other. In the new edition of the *Index* there are a few entirely new articles, notably one on hypnosis and its uses in aiding treatment by suggestion. The writer, Dr. Milne Bramwell, wisely refrains from dogmatic assertion and contents himself with the far more convincing method of stating in plain terms what has been achieved thus far and in what directions further advance may reasonably be looked for. It has sometimes been supposed that the higher types of intellect are more susceptible to suggestion than others, but the cases quoted would go to prove that a very considerable amount of success has been achieved among the debased and degenerate types. The patient has been taught to control his own organism. Climatic treatment is accorded a place in the new volume, and the description given by Dr. Leonard Williams of the various types of health resort, of necessity somewhat curtailed, will be found most useful as a guide not only to the selection of a suitable place but also to the avoidance of the unsuitable. The comments and recommendations are marked by strong common sense. Dr. Calvert has contributed a short article on certain points in prescribing and the incompatibility of some common combinations which should be specially noted. The whole work maintains its high level of accuracy and usefulness.

In response to the publisher's invitation, Dr. ARTHUR LATHAM has compiled a small *Dictionary of Treatment*,⁴ for which, after exhaustively testing it, we have nothing but praise. Within the compass of a volume not too large for a pocket will be found a concise, but by no means meagre, account of the best methods of dealing with almost every disease that is likely to come within the experience of the busiest practitioner. It is essentially a handbook of reference for the busy man. By means of heavy type its headings and cross-references are rapidly found, and the information conveyed under each, although of necessity somewhat dogmatically stated, is at once singularly comprehensive and clear, although expressed in very few words. Only in dealing with some of the newer methods, such, for instance, as vaccine therapy, does the writer dilate at all upon his subject. The reader will do well to study carefully, sometimes reading between the lines, the section descriptive of vaccine treatment in general. Whatever the future may have in store, it is evident that at the present time these procedures ought to be employed with the utmost caution. The sections relating to diet and the feeding of infants are particularly worthy of note, and the general instructions for dealing with tuberculosis, and many other much-debated diseases, are marked by strong common sense. The little book is a veritable mine of trustworthy information.

HYDROTHERAPY, ETC.

Dr. T. D. LUKE's *Manual of Natural Therapy*,⁵ is a concise volume corresponding to the manuals of physical and dietetic therapy in use on the Continent. In other

¹ *Die Perkussion in der Bestimmung der Herzgrößen* (Perkussion in the Determination of the Heart's Boundaries: A Historical, Critical, and Clinical Study). By Dr. Anast. Araventinus, of Athens. Berlin: Max. Günther. 1907. (Cr. 4to, pp. 80.)

² *Arterio-Sclerosis*. By Louis M. Warfield, A.B., M.D., with an introduction by W. S. Thayer, M.D., Professor of Clinical Medicine, Johns Hopkins University. St. Louis, Mo.: C. V. Mosby Medical Book Co. 1908. (Imp. roy. 8vo, pp. 192, 8 illustrations.)

³ *An Index of Treatment by Various Writers*. Edited by Robert Hutchison, M.D., F.R.C.P., Physician to the London Hospital, and H. Stansfield Collier, F.R.C.S., Surgeon to St. Mary's Hospital. Fourth edition. Revised: John Wright and Co., London. Stimpkin, Marshall and Co., and New York: Williams Wood and Co. 1908. (Demy 8vo, pp. 942, 21s.)

⁴ *A Dictionary of Medical Treatment for Students and Junior Practitioners*. By Arthur Latham, M.A., M.D. (Oxon.). Physician to St. George's Hospital, etc. London: J. and A. Churchill. 1908. (Cr. 8vo, pp. 325, 6s. 6d.)

⁵ *A Manual of Natural Therapy*. By Thomas D. Luke, F.R.C.S. (Edin.). Bristol: J. Wright and Sons. 1908. (Demy 8vo, pp. 312; with 30 plates and 125 illustrations. 7s. 6d.)

words, it is a practical manual of therapeutic methods other than those by drug-giving, and embraces most of the ground occupied by the numerous volumes of Solis Cohen's *System of Physiologic Therapeutics* and by the large *Handbuch der physikalischen Therapie*, edited in Germany by Goldscheider and Jacob. The book is divided into six sections, of which the first and probably the most important is devoted to the use of water in the treatment of disease, including the use of peat, "fango," and medicated baths. The succeeding sections deal with heat and light, massage and rest cures, electricity, and diet, in the treatment of disease. In the sixth section the modern "cure" in hydropathic establishments and sanatoriums and by foreign mineral waters is discussed. A great advantage of the book consists in the author's precision and clearness when he enters upon the principles involved in the different methods of treatment. For instance, in Chapter II the general principles of hydrotherapy are admirably explained, and very much to the point are his remarks (pp. 281, 282) on treatment at establishments. The Roman inscription which he quotes from the baths of Caracalla—

fed deder per-Curæ vacuus luno adeas locum
Ut morborum vacuus abire queas,
Hic enim non curatur qui curat—

suggests, however, that in some cases successful treatment is likely to be more easily obtained at places rather distant from home than at any in the neighbourhood. This is, doubtless, recognized by many of our kinsmen from the other side of the globe, who every year help to throng the health resorts of Europe. On p. 8 the author refers to "American physicians, such as Kisch, Baruch, and Kellogg." Surely he refers to the Marienbad physician. Dr. E. H. Kisch, supposing him to be American because he contributed to a well-known American textbook on the subject. On p. 28 the author's reasonings lead him to conclude that a condition of "hydraemic plethora" is an impossibility, but chlorosis is not a very rare disease, and the researches of Lorrain Smith (1900) have shown that in chlorosis the total blood volume is excessive, and that, therefore, the condition may almost be termed one of "hydraemic plethora." On the whole, the book will probably be found very useful to many medical practitioners, though some may object that the author's use of the term "natural therapy" suggests that other treatment (by drugs) is "unnatural."

CONGENITAL TUBERCULOSIS.

Dr. SITZENFREY, in his monograph on congenital tuberculosis, reviews the literature of the subject, and describes his investigations of twenty-six placentas of tuberculous mothers. In addition to the placentas, the fetal membranes, the umbilical cords, and the newly born infants which came to the *post-mortem* room were also examined. The author finds that the extent of disease in the offspring is proportionate to the intensity of the tuberculous process found in the placenta. Thus, in one case in which the placenta was riddled with miliary tubercles and larger tuberculous foci the child died four-hours after birth; in another case, in which the placental tubercles were relatively scanty, the child succumbed, when three months old, to a chronic pulmonary tuberculosis, with bilateral tuberculous pleurisy; and in a third case, in which, after patient search, no more than one tuberculous focus could be discovered in the placenta, the child is still alive and well. Dr. Sitzenfrey is of opinion that white infarcts afford a particularly favourable site for the development of tubercles. Both fetal and maternal elements contribute to the structure of villous tubercles, with the exception of the so-called "primary villous tubercle," which is formed from fetal elements alone. The epithelioid and giant cells are derivatives of the cells constituting the stroma of the villi or of the vascular endothelium. With regard to the significance of the placental vascular system in the possible transmission of tuberculosis, Dr. Sitzenfrey points out that long-continued engorgement of the villous capillaries may lead to rupture of these vessels into the maternal intervillous spaces; then the possibility arises that subsequent lowering of the vascular pressure in the villous tufts may

permit the entrance of maternal blood, and so allow the transference from the maternal to the fetal vascular system of tubercle bacilli which may be circulating in the former. Again, when the tuberculous changes are localized exclusively in the decidua vera, these foci may penetrate the amnion, infect the liquor amnii, and in this way lead to intrauterine infection of the fetus. The author has also succeeded in demonstrating the presence of tuberculous changes within the vessels of the umbilical cord. Dr. Sitzenfrey's book is an interesting and important contribution to the study of congenital tuberculosis, and may be thoroughly recommended to the attention of our readers.

NOTES ON BOOKS.

DR. ALEX HILL is to be congratulated upon the admirable conception and excellent execution which has resulted in the production of his account of *The Body at Work*.¹⁰ The book satisfies a long-felt want and constitutes a textbook of physiology adapted to the use of the general public, for it is written in words whose meaning must be plain to any one who has a moderate acquaintance with the English language, and no preliminary knowledge of chemistry and physics is necessary for the comprehension of Dr. Hill's statements regarding the phenomena of bodily activity. In a book intended for the general reader, the phenomena associated with reproduction are not easily dealt with, and we think Dr. Hill has been wise in excluding them from this volume. All the other important phenomena are dealt with in a descriptive rather than a detailed and critical manner, with the result that the reader is presented with very clear and definite word pictures of the initiation, progress, and termination of the various bodily processes. In other words, Dr. Hill has adopted the dogmatic method of teaching, which is undoubtedly the one best adapted for his purpose. Though the book is not primarily intended for medical students, they will nevertheless find it an excellent introduction to more detailed study.

The third edition of Captain C. A. THIMMS'S *Hindustani Self Taught*¹¹ has been edited and revised by Professor I. F. Blumhardt, M.A. While the plan and general arrangement of the book have been preserved, useful alterations and additions have been made in order to render it more easy and useful as an introduction to *Hindustani* as a spoken language. The words and subjects of conversation selected are those likely to be of practical service to travellers and residents in India. Some of the phrases are perhaps more classical than those employed in common talk, but the patois of servants and coolies, which varies in different parts of the country, could hardly be introduced into a guide to the *lingua franca* of the whole continent.

*Truth's Dictionary List*¹² for 1909 has been issued in a small bound volume. It contains the names of various individuals, organizations, and firms which have incurred unfavourable notice in *Truth*. That it is found useful appears from the fact that five editions were called for last year. This year the scope has been extended to cover two complete years and references are given to the page and volume of *Truth* in which fuller details are to be found. The names are classified under a number of headings, one of the longest sections being that devoted to "medical quacks," a large proportion of the names in this part of the list being of transatlantic origin. In the introduction to this section attention is called to the fact that many of these persons "while declared under a 'fraud order' from using the mails in the United States, are allowed to carry on their business in this country with perfect immunity from interference." Yet that the law is strong enough to deal with the more flagrant forms of quackery has been demonstrated by the recent convictions of Hawkins and Montague at the Lewis Assizes.

¹¹ *Hindustani Self Taught, with English Phonetic Pronunciation*, By Captain C. A. Thimms. Third edition. Revised by I. F. Blumhardt, M.A., M.B.A.S. London: E. Marlborough and Co. 1908. (Cr. 8vo, pp. 112, 2s., cloth 2s. 6d.)

¹² London: *Truth* Offices, 1909. (Cr. 8vo, pp. 94, 1s., post free, 1s. 1d.)

¹³ *Die Lehre von der kongenitalen Tuberkulose, mit besonderer Berücksichtigung der Placentartuberkulose*. Von Dr. Anton Sitzenfrey. Berlin: S. Karger, 1909. (Sup. roy. 8vo, pp. 156, 28 illustrations in the text. M. 5.50.)

A GERMAN Central Committee for the care of the teeth of school children was constituted on February 1st. The Honorary President is Dr. von Stundt, Minister of State, the President, Dr. von Moeller, Minister of State. Among the members of the committee are Professor Kirchner and Professor Williger.

MEDICINAL AND DIETETIC PREPARATIONS.

Pills of Phenolphthalein with Aloin, etc.

ALTHOUGH the value of phenolphthalein as an aperient is of quite recent discovery, its use for this purpose is already large. Messrs. Parke, Davis, and Co. (Beak Street, London, W.) have submitted samples of a pill containing phenolphthalein, aloin, strychnine, belladonna, and ipecacuanha, which is recommended for the treatment of chronic constipation, as well as for the relief of migraine, and in other cases. The pills are gelatine coated, and we found the coating to be soluble in a few minutes at body temperature. The combination should prove useful.

Vegetable Fat for Cooking.

We have examined a sample of a vegetable fat for cooking purposes, supplied by the Vegetable Butter Company (6, Trinity Square, London, E.C.) under the name "Palmino." It consists of a pure white fat, odourless and practically tasteless; it melts at 25°C. (77°F.), and appears from the results of analysis to be a pure refined coconut oil; it is practically neutral (the "acid value" being only 0.25), and, having a very low iodine-absorption value, is not prone to rancidity. To those who object to employing animal fat in cooking, Palmino will no doubt prove acceptable. Further, a fat which, like this, is free from flavour, and contains neither water nor other non-fatty constituents, has a suitable melting point and is free from rancidity, is likely to prove a serious rival to lard, dripping, etc., even with those who have no objection to the latter on the score of their source.

ROYAL COMMISSION ON VIVISECTION.

FOURTH REPORT.

(Concluded from page 415.)

THIS week we conclude our abstracts of the evidence given before the Royal Commission on Vivisection.*

Evidence of Professor D. J. Hamilton.

Professor Hamilton gave evidence on behalf of the University of Aberdeen, which only desired him to give evidence about some special inquiries which he had made with regard to diseases in sheep, in the course of which recourse was had to experiments on animals. The experiments were first carried on privately and afterwards at the suggestion of the Highland and Agricultural Society. He was Chairman of a Departmental Committee which was appointed by the Board of Agriculture in 1901, and which issued its Report in 1905. In that Report there was a detailed account of the researches which had been spread over four years. The object was to investigate louping-ill (*chorea paralytica ovis*) and braxy. These two diseases of sheep were the cause of enormous mortality all over Great Britain, especially in Scotland, the northern counties of England, and also in Ireland. The mortality was so great that in certain districts sheep farming as a profitable industry was threatened with extinction. That had been going on for a great many years, and some parts of Scotland had become depopulated on account of the enormous loss. A quarter of a million, it was said, was lost annually from braxy alone, and that was probably an under-estimate. In the case of braxy he had known, from his own experience, 10 to 15, 25, 50, 80, and 100 per cent. of mortality over certain districts on certain farms. From louping-ill the mortality was usually not so high, but sometimes came up to 15, and 20 to 25 per cent. There was great interference with business, not only in the transference of sheep, but in the whole farming operations. With regard to louping-ill, their first experience was gained in the valley of the North Tyne, where the Duke of Northumberland fitted up a station so that they could undertake the investigation. Most of his experiments on that disease were carried out in that neighbourhood. The first symptom was that the sheep appeared dull, and separated itself from other sheep; it then showed more or less pronounced toxic symptoms, looked as if it was suffering from alcoholic intoxication,

with a reeling gait, giddiness, and a tendency to lean up against any support. In forty-eight to sixty hours afterwards the animal fell over on its side, and then passed into the second stage of the disease, in which it was convulsed, contracted, and so on. In four or five days the animal passed into the third stage, in which it became more or less paralysed in all its extremities. Usually within a week or ten days after the commencement of the disease it died. The great majority of cases terminated fatally. They began by studying the phenomena by visual and other external means of examination and examination of the carcasses of animals that had died. In the vast majority of cases, if one saw the animal immediately after death, or if one slaughtered it in the height of the disease, the organs appeared to be practically healthy; a few punctiform hæmorrhages along the intestine were perhaps the only residue found. He could never find anything wrong with the blood. They produced no result by inoculating the blood; nor did the cerebro-spinal fluid produce any apparent effect. As a last resource they investigated the liquid in the peritoneal cavity, which very often presented a turbid appearance, especially a few hours after death, and on inoculating this subcutaneously they killed the inoculated animal practically in every case. In the intestine sometimes the bacillus was found in tremendous numbers. It resembled the anthrax bacillus, but grew differently; probably there was a certain relationship between them. After inoculation under the skin the animal usually died in from thirty-six to forty-eight hours. Some cases, however, were protracted over four or five days. In such cases he had seen the most perfect reproduction of the disease, not only in the sheep, but also in the rabbit. The conclusions they came to were that the disease was caused by a specific bacillus inhabiting the intestine, and under certain circumstances getting into the peritoneal cavity. They also concluded that the disease was spread through the dejecta of the animal through the manure, and also through the carelessness of farmers in leaving the carcasses about everywhere. The spores would lie in the soil for a long time apparently, and they were taken up by a second sheep, and in that way the disease was reproduced. Braxy was due to an organism of the same nature, although not identical with that of louping-ill. It was originally discovered in Norway by Nielsen by experimenting on living animals. Their investigations corroborated that discovery. The habitat was the same as that in louping-ill. The symptoms were quite different. It got the name of braxy, he believed, from an old Scandinavian derivation, signifying the suddenness of the fatality of the disease. "Beadsot" it was called in Scandinavia, and the word "braxy" was probably a lineal descendant of that. When an animal was attacked with either of these diseases treatment had very little effect upon it. Segregation had been tried over and over again. Immunization was the only feasible remedy so far. They found that the introduction of the organism in an attenuated condition, although it apparently produced a certain amount of immunity, was dangerous. Moreover, the carrying out of this method on a large scale in sheep-farming districts was impracticable, because it entailed the use of a delicate instrument in unskilled hands. Hence it was given up. Braxy was essentially a disease of first-year sheep. Farmers looked upon their two-year-olds as practically safe. That suggested that immunity, if it was acquired, must be acquired through some agency residing in the soil, and the idea struck them that the spores of the organism getting into the alimentary canal were Nature's agent in inducing this immunity. There were certain months of the year in which sheep were more susceptible to the disease. It began usually in September and went on to about the middle or end of February. His strong impression was—and he had heard it from sheep farmers—that all the animals passed through a mild attack of the disease. The organism was got in a pure state first and isolated in a pure condition; after that it was grown artificially from the peritoneal liquid. Then this was administered as a drench by the mouth. That was done at the time when sheep were practically immune from the disease—in August. They had experimented for several years progressively, modifying the method and studying what the effect would be over a whole braxy season, to ascertain what would be an effective dose, and in what form the bacillus

* London: Printed for His Majesty's Stationery Office, by Wyman and Sons, Limited, 109, Fetter Lane, E.C. And to be purchased, either directly or through any bookseller, from Wyman and Sons, 109, Fetter Lane, Fleet Street, E.C.; and 24, Abingdon Street, Westminster, S.W.; or Oliver and Boyd, Edinburgh; or E. Ponsouby, 416, Grafton Street, Dublin. (1908.)

ought to be administered. They had obtained fair success, but by no means what they anticipated in the way of still further progress. It was all done by experiments on living sheep and on rabbits and guinea-pigs. There was very good evidence to show that they had arrived at a true immunizing remedy. What was defective still was apparently the method of preparing it. He thought they would prepare it in the spore stage instead of the bacillary stage, and if so, there would be a much better chance of its immunizing the animal. During August, 1906, they treated some 13,000 sheep, and in February, 1907, some 4,000. He was speaking of both braxy and louping-ill. A very important point was to make out experimentally whether one could immunize an animal against braxy and louping-ill at the same time, as that would mean that one could save the farmer gathering his sheep twice or three times a year. These experiments were still going on. Asked to what extent he could say he had ascertained any benefit to the flocks, he said it would perhaps serve the purpose of the Commission if he gave an individual instance. A proprietor on the west coast of Scotland who was determined that he would see the experiment carried out properly, took the very greatest pains. He made the crucial experiment of drenching 400 sheep. That composed his whole stock of first-year sheep except 20. They were put under exactly the same circumstances, the first lot treated against braxy, the second lot in its natural state. Of the 400 drenched sheep, he lost 30 up to the end of May, many of them, it was said, from louping-ill. The witness examined the peritoneal liquid from the carcasses of 11 of these, and could not discover that there were any deaths from braxy, or only two, which were doubtful. Thirty out of 400 he lost from all causes, whereas in the case of the 20 undrenched sheep he lost 19. Very few of the 30, if any, died from braxy; in the others there was no doubt about the presence of braxy. That had been his invariable experience. There were some braxy-like diseases which were continually called braxy among farming people, but these differed from braxy in the scientific sense of the term. They concluded from the returns they got, the evidence they heard, and the examination of the peritoneal liquid, that, with certain exceptions, the mortality in the cases treated by them was considerably lower than in those not treated. When he said, "with certain exceptions," he meant on certain farms where apparently the disease they suffered from was not braxy at all; it was very often a disease known as blackquarter. The animals did not seem to suffer the slightest pain when the preventive was administered by the mouth, except that they were a little upset for a day or two, and giddy occasionally. If his experiments were successful, even to the extent of reducing the prevalence of braxy 5 per cent., that would mean enormously more lives saved than were lost by experiments. He thought they were on the lines calculated to prevent the diseases; he had never seen anything that did any good when once the animal was attacked by braxy. He thought they had the means by bacteriological investigation of discriminating accurately between braxy, blackquarter, malignant oedema, and louping-ill. They doubtless belonged to a family, and they had certain points in common. In the matter of growth and some other points it had a resemblance to anthrax. He had tried protecting sheep against all the diseases simultaneously. He did not know yet if it had been successful; it was being tried by mixing the preventive fluids against the four diseases. The evidence pointed to the fact that louping-ill was communicated by ingestion rather than by inoculation. The immunity in braxy seemed, in the majority of cases, to last the lifetime—that was, from two to two and a half years in the case of animals for slaughter. As in the case of small-pox, there were found exceptions here and there. He was not so sure with louping-ill whether that was so. Two-year old sheep took the disease, and it was said sometimes took it twice. But it tided the animal over the louping-ill season, and that was the great point. The investigations had been followed with great interest by the agricultural community of Scotland, and so far as he knew the line of investigation pursued had had their approval. Asked what he thought would be the general feeling of agriculturists in Scotland with regard to a proposal that experiments on animals with a view to extend knowledge as to human or animal disease should be prohibited by law,

Professor Hamilton said that from conversation and wide experience he had had with intelligent farmers he thought it would raise a *furor* among the intelligent agricultural population if anything of the kind were attempted. In reply to questions, he said that without a travelling licence he could not have effectively experimented without breaking the law. He would not trust to laboratory experiments exclusively on a matter of that kind. With certain exceptions here and there on particular farms and in particular districts, the returns, so far as braxy was concerned, had shown that the mortality in the drenched was very considerably lower than in the undrenched districts. They had a very great deal to learn yet, but he was thoroughly confident they would be able to combat the disease. He had had every encouragement from farmers in the attempt to immunize their sheep by drenching. A shepherd could carry out the immunizing proceeding by drenching perfectly well. No attenuation to any extent was caused by the method of cultivation. In the natural disease exposure to weather might have the effect of attenuating the organism to a certain extent. Their method was to give a mild form of the disease at the time of year at which the animal was not naturally subject to it, so as to cause immunity. If given at other times of the year they would be killed in great numbers. The inoculation experiments conferred undoubtedly a certain immunity, but the difficulty was in the administration of the system in unskilled hands. Proceeding, he said it was his opinion—and he thought that of the Medical Faculty of the University of Aberdeen—that the existing Act should continue. In reply to further questions, he said the method of drenching had been employed for the prevention of pleuropneumonia of cattle, for instance, but he did not know that it had been applied to these diseases of sheep, nor by the method he had described. He would not say that drenching had not been a method in use, but it had been applied empirically. Of late the alimentary canal had been looked upon as the source from which one could treat several contagious diseases and produce immunity, and much more so than formerly. Asked as to the system of preventive treatment followed in bygone days of drenching with the dung of pigs fed on pasture covered with the manure of sheep, he said they supposed that this pigs' manure treatment of these diseases (which was a thoroughly empirical one) had nothing in it at first; however, the farmers were so positive about its virtues, that they made further inquiry into it, and after they discovered the intestinal habitat of the organisms they were dealing with, the explanation was afforded of how the pigs' manure might act as a prophylactic, because it might contain the bacillus. The pig was always put out to feed upon the grass over which the sheep were grazing, the manure was collected after it had been upon the grass. The manure was filled with spores of some kind, most likely the spores which were the cause of the disease in the sheep, and if one administered the manure to the sheep an immunity was conferred upon the animal. He did not know whether his experiments had been repeated by any Norwegian bacteriologists, but the Norwegian Government had sent a representative from their Agricultural Department to learn about them. He had also had a good deal of correspondence on the subject with Professor Jensen of Copenhagen. He had had no evidence of his experiments being disputed or confirmed. The inquiry was still incomplete. Proceeding, he said that on the majority of farms the experiments had succeeded wonderfully well; on other farms they had been a failure; the mortality had been fairly high, and apparently for a very good reason. The sheep were treated for one disease and they died from something else. The prophylactic was prepared by himself. They had usually distributed it to the farmers free until the previous year, and, he thought, part of the foregoing year (1907 and part of 1906) when they had to make a small charge for it. The applications were so numerous that the preparation was attended with a fair amount of expense, and they made a small charge for it, which was willingly paid. Asked if there was any risk in eating braxy mutton, he said there was no other animal except the sheep that took braxy. He did not know that he would like to eat braxy mutton himself, but other people did, and it did them no harm, apparently. Dogs and other animals ate the carcasses with impunity.

Nova et Vetera.

THE MADNESS OF TASSO.

Much has been written and still more conjectured and even invented, about the poet Tasso; and in these days, as in his own, opinions differ widely concerning him. The interest of this fresh work on *Tasso and His Times*¹ lies in the fact that it is written from a more or less new standpoint, that of a medical man.

The author has brushed aside the legends which cluster so thickly round Tasso's name, and has set himself out to trace the course of his malady, and its effects upon his mind and character. The gradual deterioration of the courtier-poet, the friend of princes and scholars and the admiration of all Italy, the decay of a brilliant intellect and the souring of a naturally sweet and unsuspecting nature, is a pitiful story, and is told with sympathy and insight by Dr. Boulting, who incidentally gives us a vivid picture of the life of a man of letters during the latter half of the sixteenth century. The Italian princes were generous patrons of art and literature, and their courts were refuges for needy genius. Each little potentate had a crowd of poets, painters, and scholars dependent upon him; he treated them almost invariably with great kindness. Yet one cannot help suspecting that it was not only the love of learning which led these dukes and marquises to surround themselves with the most learned and famous men of their day, but also the hope that their own names might shine the brighter by the reflected glory of those around them. Their intense jealousy in regard to each other's "lions," and the intrigues and bribes used to draw them from each other's courts, seem to confirm this view, and throws a curious light on the times when beauty and wisdom in all their forms were worshipped so fervently.

The relations between the patron and his protégé were those of master and servant, and the poet dependent upon a sixteenth century prince was entirely in his power. Yet many enduring friendships were formed between scholars and artists and their protectors. Tasso was intimate with several members of the various noble houses he served, and some of these, in spite of quarrels and ingratitude, remained his devoted friends and admirers to the end.

Torquato Tasso was born at Sorrento in 1544. He was the son of Bernardo Tasso and Porzia de' Rossi, and the descendant of a noble family of Bergamo. His father was celebrated throughout Italy as a soldier, courtier, and poet, and Torquato was destined for a Court career, the only opening in those days for young men of short purses and long pedigrees. Brought up at the Court of the Duke of Urbino, he went through a course of study at the University of Padua, and then entered the service, first, of Cardinal Luigi d'Este, brother of Alfonso II, Duke of Ferrara, and then that of the Duke himself. "Torquato was a born courtier," says his biographer, and at Ferrara he was in his element. He became the friend and companion of Alfonso and his sisters, the Princesses Lucrezia and Leonora, and plunged into a life of feverish excitement and activity, both mental and physical. It was a life that would have worn out the strongest, and Tasso was not a strong man. From his earliest childhood and throughout his youth he persistently burned the candle at both ends, and to this Dr. Boulting attributes his mental breakdown. The old stories that Tasso went mad for love of Leonora d'Este, or else was forced by Alfonso to feign insanity as a punishment for winning his sister's love, he looks upon as mere myths; indeed, he goes so far as to deny the truth of Tasso's ever having been in love with Leonora at all.

Overstudy in childhood and the terrible strain of later years were the cause of his trouble. The first signs of mental disturbance appeared in the year 1575, when his health began to fail. He grew irritable and suspicious, imagined himself slighted and insulted by his friends and betrayed by his servants; he fancied that he had been denounced to the Inquisition, and lived in daily fear of being poisoned by his enemies. He was tormented by religious doubts and fears, and to crown all, he was full of anxiety concerning his masterpiece, the *Gerusalemme Liberata*.

It is not surprising that his brain gave way under such a strain, though the process was a gradual one. The Duke, seeing his state, treated him with the greatest possible kindness, sending him to one of his country houses for rest and change of air, and putting him under the care of his own doctors. By these learned men Tasso was bled and purged; but he himself had great faith in a certain Ferrarese druggist, who undertook to cure him in a few days. Perhaps, on the whole, it was lucky for Tasso that Lucrezia d'Este commanded the chemist to take his orders from the Court physician, who prescribed blood-letting, with a course of white wine to follow. Tasso, however, grew worse and worse; and it must be admitted that he was a sore trial to the friends who were doing their best for him. Not only did he pour forth his grievances against the Duke in wonderfully sane and plausible letters addressed to all his friends and neighbouring princes, but he was consumed with anxiety about the souls of Alfonso and his courtiers. He suspected them of heresy, and wished to go to Rome to denounce them to the Inquisition. Alfonso put up with him for a long time. When one considers the absolute power of an Italian prince in those days one cannot help acknowledging that Tasso's patron behaved with great forbearance, but his patience gave out when the poet drew his knife on a servant in the presence of the Princess Lucrezia. This was in the summer of 1577, and Tasso was imprisoned for a short time. He was very quickly released and sent to one of the ducal country houses for a change, but soon asked for permission to go to the Monastery of San Francesco. Here he spent his time in going to confession, and writing to the Inquisition. The monks tended him with great care, but he suspected them of playing tricks with his wine, and wrote to complain of this to the Duke.

When he became too great a responsibility for the monks he was taken back to the Castello at Ferrara, where he was lodged in his own rooms with a couple of attendants to look after him, and a grille across the window. He managed to escape, however, and spent some time at Sorrento with his sister. Then he began to long for the gay life of the Court, and the Duke consented to take him back to Ferrara on the condition that he would submit to a course of medical treatment. Tasso had private apartments, not in the palace, and here he lived for a time. His doctor's prescriptions have been found amongst the papers of the Estensi; they consist chiefly of calmatives, sleeping draughts, and purges. In the summer of 1578 he ran away again, and wandered through Mantua, Padua, Venice, Urbino, and Lombardy. Wherever he went he met with unflinching kindness, and the honour due to a distinguished poet. He was sheltered and kept by the great reigning houses of Italy till he grew weary of them, and wore out their patience with his suspicions and irritability. In 1579 Duke Alfonso again took him back to Ferrara. It was just at the time of his third marriage, and in the bustle of the wedding festivities Tasso imagined himself neglected. He brooded over this fancied slight till his brain gave way utterly. One day he flew into a maniacal fury, and was taken to the hospital of St. Anna a raving lunatic. That was in March, 1579, and he remained there till July, 1586. The hospital had certain rooms set apart for maniacs, and on his arrival Tasso was put into one of these, and chained down. The chain served the purpose of a straight waistcoat, and was a necessity at first, for Tasso had assaulted and beaten one of his warders. His place of confinement, however, was not the gloomy cell in which Goethe and Byron have inscribed their names, but a much airier room; and, when he grew calmer, his chain was removed, and he was given a much better apartment. After the first few months of his imprisonment he lived in large and well-furnished rooms, received visits from his friends, was allowed to write to anyone he wished, and even went out, attended by responsible persons. He was allowed to spend a day with the Marchesa of Massa and Carrara at her Villa di Madalera, and stayed at Belvedere with Lucrezia d'Este. The history of his seven years at St. Anna is a proof that the treatment of the insane at that period in Italy was as humane and enlightened as it was in some parts of Spain in the previous century. There is no hint of the horrors prevalent in the asylums of our own country at a much later date. Tasso's mental condition varied greatly during this time—fits of excitement

¹*Tasso and His Times*. By William Boulting. London: Methuen and Co. (Pp. 307. 10s. 6d.)

were followed by a terrible depression; he was caused great grief by the deprivation of religious consolation, for, though lunatics were treated with unusual consideration in Italy, they were denied both confession and communion. In 1586 Tasso was invited to Mantua by the prince of that city, and, greatly against the wishes of the Duke, he left Ferrara for the last time. Thenceforth his life consisted of ceaseless wanderings from town to town, from court to court. Dr. Boulting clearly brings out the progressive deterioration which brain disease wrought not only in the poet's mind but in his character. He had only been a few months at Mantua when he considered himself slighted, and left the Court for Bologna. Thence he travelled to Loreto and Rome, then to Naples, Florence, and Mantua, then back to Rome and Naples, always poor, always ill, and tortured with anxiety about his writings and his religion. Princes, cardinals, patriarchs, even popes, offered him shelter, but he could not rest. His weary pilgrimage ended at Rome on April 25th, 1595, when he died at the Convent of San Onofrio, where his last days had been spent.

Dr. Boulting has told the sad story in a sympathetic spirit and with much literary skill. The book, on nearly every page of which there is evidence of scholarly research, should be especially interesting to medical men as it deals with a remarkable case affording valuable material for the study of morbid psychology.

MIDLAND MEDICAL UNION.

ON Wednesday, February 10th, the annual meeting of the Midland Medical Union was held at Chesterfield, Dr. R. G. ALLEN (of Belper), President of the Union, in the chair. The annual report was presented and adopted, and the accounts for the year as audited were passed. A vote of thanks was accorded to Dr. R. G. Allen, the retiring President, for the care and attention he had devoted to the work of the Union during a very busy year. Mr. Josiah Court, J.P., of Staveley, was elected President for the ensuing year. The Council and other honorary officers were elected, and the General Secretary (Mr. G. S. O'Rorke, LL.D., of Nottingham) was reappointed.

Proposed Amalgamation with the British Medical Association.

After careful discussion, it was resolved that the Union approach the British Medical Association with a view to becoming (without losing its identity) a committee of that association in a manner similar to that adopted in the case of the Durham Medical Union. A referendum taken by postcard was read, from which it appeared that the majority of the members were in favour of the proposal. It was further resolved that the matter be referred to the consideration of two subcommittees, one for the Nottingham Division of the Union, and the other for the Derby Division, and that (subject to their consent) the following gentlemen be appointed, with power to add to their number:

Nottingham Subcommittee.—Messrs. J. H. Cox and J. Mackie, Drs. F. R. Mutch, A. Fulton, and W. H. Hill.

Derby Subcommittee.—Messrs. J. Court, J.P., and R. G. Allen, Drs. G. Booth, J.P., J. A. Goodfellow, and A. Green.

Dr. T. HENDERSON, Honorary Secretary Nottingham Division of the British Medical Association, who was present by invitation, spoke in favour of the proposal. Dr. W. St. A. St. John, Honorary Secretary of the Derbyshire Division of the British Medical Association, was also present.

Dinner.

After the meeting, the annual dinner was held at the Hotel Portland under the presidency of Mr. R. G. Allen (in the absence through illness of the newly-elected President, Mr. J. Court). Amongst those present were the Mayor (Mr. S. E. Short) and Mayoress of Chesterfield, Mrs. R. G. Allen, Dr. W. Dyson, J.P., Sinclair White, and Mrs. Wilkinson, A. Hall, Dr. Burgess, J. G. Shea, J.P., and Mrs. Shea, G. Booth, Mr. V. E. Sutcliffe and Mrs. Sutcliffe, Mr. F. J. Waldmeier, Dr. and Mrs. J. A. Goodfellow and Dr. R. A. McCrae, Dr. T. Henderson, Mr. J. A. Magee, Dr. and Mrs. W. C. Rainsbury, Dr. R. Godwin Chase, the Rev. W. F. Dutton, M.A., and Mr. G. S. O'Rorke, LL.D., General Secretary.

The loyal toasts were proposed by the CHAIRMAN and were cordially received. The toast of "The Midland Medical Union" was proposed by Dr. ARTHUR HALL (Sheffield) and acknowledged by the CHAIRMAN. The toast of "The Guests" was submitted by Dr. J. G. SHEA, and after a hearty reception was acknowledged in felicitous terms by the Mayor. The remainder of the evening was devoted to music, Miss Jackson Lee (soprano), of Sheffield, and the Cavendish Quartette being present, and a most enjoyable evening was spent.

THE PLAGUE.

PREVALENCE OF THE DISEASE.

DURING the weeks ended November 14th, 25th, December 5th, 12th, 19th, 26th (1908), January 2nd, 9th, and 16th (1909), the deaths from plague in India amounted to 1,621, 1,646, 1,626, 1,583, 1,788, 1,683, 1,431, 2,155, and 1,991 respectively. The returns show a gratifying decline compared with any year since plague first appeared in India in 1896. The mortality returns for the year 1908 show that the number of deaths from plague in India amounted to about 148,700 only, compared with 1,315,892 during 1907. The year 1909 opens with no signs of any serious recrudescence of the disease.

The distribution of plague in India may be gathered from the following figures: During the week ended November 21st, 1908, the mortality from plague was—in Bombay Presidency, 782; Bengal, 71; United Provinces, 52; Punjab, 275; Central Provinces, 104; Central India, 64; Hyderabad State, 20; Madras Presidency, 48; Mysore State, 162; Burma, 43. During the week ended January 16th, 1909, the figures were: Bombay Presidency, 475; Bengal, 188; United Provinces, 231; Punjab, 589; Central Provinces, 198; Central India no deaths reported since December 13th, when 16 were announced; Hyderabad State (last report December 19th—10 deaths announced); Madras Presidency, 17; Mysore State (no returns); Burma, 312.

MARITIMES.

During the weeks ended December 17th, 24th, 31st (1908), and January 7th, 14th, 21st, 28th, and February 4th and 11th (1909), the fresh cases of plague in Mauritius numbered 15, 15, 4, 2, 4, 4, 1, and 1; the deaths during these weeks amounted to 10, 9, 4, 1, 2, 3, 1, and 1 respectively.

GERMAN EAST AFRICA.

On November 24th a fresh case of plague occurred.

BRITISH EAST AFRICA.

Kisumu declared free from plague.

ZANZIBAR.

On November 22nd, 1908, 2 fresh cases reported.

EGYPT.

Between November 10th and December 25th, 1908, 193 fresh cases of plague reported, and 44 deaths from the disease. In Alexandria 3 cases reported, and in Port Said 1.

TRIPLEX.

In Bagdad, from November 6th, 1908, to January 5th, 1909, fresh cases reported, 31; deaths from the disease, 7.

In Beirut, 5 fatal cases of pneumonic plague reported on January 2nd, 1909.

STRAITS SETTLEMENTS.

On November 2nd, 1908, 1 case of plague reported.

FORMOSA.

Between November 7th and 14th, 1908, fresh cases of plague, 17; and 5 deaths from the disease.

CHINA.

At Tong-Shan and district plague was reported to be epidemic in November 2nd, 1908. Sporadic cases in Hong Kong reported during the past three months.

JAPAN.

Between October 13th and December 16th, 1908, the fresh cases of plague at Awa, Miochinomya, and Kobe numbered 25, 15, and 18 respectively. At Awa, of the 25 cases, 18 proved fatal. At Osaka a fresh outbreak of plague was reported on December 17th, 1908.

UNITED STATES AMERICA.

Between July 15th and December 16th, 1908, the fresh cases reported numbered 4, with 3 deaths from the disease.

BRASIL.

Rio de Janeiro.—Between August 24th and December 20th, 1908, the fresh cases of plague numbered 87 and the deaths from the disease 46.

PERU.

Between September 25th and October 28th, 1908, 68 fresh cases of plague reported, and 25 deaths from the disease.

ECUADOR.

From Guayaquil and Milagro, between November 7th and 15th, 1908, fresh cases of plague numbered 15, with 10 deaths.

AZORES.

Between July 1st and October 27th, 1908, at Terceira, 112 fresh cases of plague reported and 53 deaths from the disease.

QUEENSLAND.

On November 5th, 1908 a fatal case of plague reported at Brisbane.

REPORT OF THE Royal Commission on the Poor Laws and Relief of Distress.

This report of the Royal Commission appointed on December 4th, 1905, was issued on Wednesday last. It is a folio volume of 1,252 pages, consisting of a Majority Report filling 670 pages; memoranda and notes by individual members of the Commission filling 48 pages, and a separate or Minority Report, which contains 518 pages.

MAJORITY REPORT.

The Majority Report is signed by the Chairman, Lord George Hamilton; Dr. Kelly, Bishop of Ross, Ireland; the Right Hon. Sir Henry Robinson, K.C.B., Vice-President of the Local Government Board for Ireland; Sir Samuel B. Provis, K.C.B., Permanent Secretary to the Local Government Board for England; Mr. Frank Holdsworth Benthall, J.P., Ex-Chairman of the Bradford Board of Guardians; Dr. A. H. Downes,¹ Senior Medical Inspector for Poor-law purposes to the Local Government Board for England; the Rev. Thory Gage Gardiner, M.A.; Mr. C. S. Loch,² Secretary of the London Charity Organization Society; Mr. J. Patten Macdougall, C.B., Vice-President of the Local Government Board for Scotland; Mr. T. Hancock Nunn,³ member of Hampstead Board of Guardians; the Rev. L. R. Phelps, M.A.; Dr. William Smart, Vice-Chairman of the Oxford Board of Guardians, Adam Smith Professor of Political Economy, University of Glasgow; Mrs. Bosanquet,⁴ and Miss Octavia Hill.⁵ The reference to the Commission was:

1. Into the working of the laws relating to the relief of poor persons in the United Kingdom;
 2. Into the various means which have been adopted outside of the Poor Laws for meeting distress arising from want of employment, particularly during periods of severe industrial depression;
- And to consider and report whether any, and if so, what, modification of the Poor Laws or changes in their administration or fresh legislation for dealing with distress are advisable.

The Majority Report consists of the following nine parts:

- Part I.—Procedure.
- Part II.—Statistical Survey of Poor Law Problems.
- Part III.—Historical Sketch of the Poor Laws down to 1834.
- Part IV.—Historical Development and Present Condition of the Various Branches of the Poor Law.
- Part V.—Medical Relief.
- Part VI.—Distress due to Unemployment.
- Part VII.—Charities and the Relief of Distress.
- Part VIII.—Miscellaneous.
- Part IX.—Review of Existing Conditions and Proposed Changes.

PART I.—PROCEDURE.

In the opening passages of their report the Commissioners state that they were impressed by the immense scope of the investigation entrusted to them, and add the observation that since 1834, when the operations of the Poor Law as a whole were last brought under the consideration of a Royal Commission, there have been presented to Parliament nearly a hundred reports of inquiries into subjects connected with the Poor Law; none of these reports, however, included in their purview pauperism as a whole, and the Commissioners state that in their report there are for the first time submitted proposals involving not only large and important modifications of the Poor Law and its administration but a revision of the methods of voluntary assistance. Having regard to the magnitude of the subject, and to the fact that the Poor Law regulates daily, and almost hourly, the lives of a heterogeneous population exceeding in size that of the city of Liverpool, the Commissioners resolved to direct their efforts towards laying down principles, leaving administrators and officials

to work out the details later on. For the same reason they limited their inquiries in the main to a survey of the general operations of the Poor Law with the object of offering suggestions and guidance to the Government.

The Commissioners also took into consideration the fact that at the time of their appointment a number of official inquiries into subjects which came within their terms of reference had recently been conducted or were actually proceeding. The three rules of procedure, therefore, which they adopted with a view to limiting the scope of their inquiry were:

- (1) To consider principles and, wherever possible, to avoid details.
- (2) To avoid any attempt at inculcating or exculpating individuals or individual boards of guardians.
- (3) To accept as far as possible the evidence and recommendations of recent or current inquiries into subjects connected with their inquiry.

Under the first head of their reference the Commissioners began by inviting chairmen of boards of guardians throughout England and Wales to report any serious defects in the Poor-law system and the best remedies; subsequently a communication was sent to all boards of guardians stating that the Commission would be happy to consider any written representations. A similar letter was sent to every parish council in Scotland. Out of the 645 unions of England and Wales replies were received from 548, either from the chairmen or from the boards, or from both. A list of questions as to the working of the Unemployed Workmen Act was sent to every distress committee, and many replies were received. The number of witnesses examined was relatively small, the Commission finding it more convenient to take evidence in the form of a written statement. Among the bodies which submitted evidence were the Local Government Boards for England, Scotland, and Ireland, the British Medical Association, the chief Poor-law and charitable associations in England and Scotland, and trade unions, friendly societies, and co-operative societies.

Special Investigations.

As certain aspects of the matter referred to the Commission seemed to call for local investigation in typical districts which the Commissioners themselves could not undertake, a number of special investigators were appointed and presented reports which the Commissioners describe as valuable; they are not contained in the volume now issued.

Among these reports is one on the methods and results of the present system of administering indoor and outdoor Poor-law medical relief in certain unions in England and Wales visited for the purpose by Dr. J. C. McVail, and one on the overlapping of the work of the voluntary general hospitals with that of Poor-law medical relief in certain districts of London, by Miss Norah B. Roberts.

PART II.—STATISTICAL SURVEY OF POOR-LAW PROBLEMS.

In this part the Commissioners, after reviewing a large mass of statistics, state that Poor-law expenditure, estimated per inhabitant, has increased from 7s. 0½d. to 8s. 2½d. since 1871-1872, and is only 7½d. less than it was in 1834; while the expenditure per pauper has increased from £7 12s. 1d. to £15 12s. 6d. in the same period. The country is maintaining a multitude of paupers not far short of the numbers maintained in 1871-2, and is spending more than double the amount upon each individual. The increased expenditure has done little towards diminishing the extent of pauperism.

Medical Relief: Poor-law Infirmeries.

The Commissioners find that there has been an increase in the number of the able-bodied sick relieved indoors since 1891-2—the first year for which statistics are available—and that this increase has been fairly general in both urban and rural areas, but has been highest in some of the urban groups of unions. It is thought probable that this is to be attributed to the development of separate Poor-law infirmeries, which has rendered the receipt of indoor medical treatment less distasteful; the number rose from 78,319 on January 1st, 1904, to 91,738 on January 1st, 1908. The Commissioners believe that over three-fourths of the poor under medical treat-

¹ Mr. Loch, Mr. Nunn, Mrs. Bosanquet, and Miss Octavia Hill sign subject to memoranda appended to the Report. Dr. Downes signed subject to a memorandum, making a note detaching himself from the schemes of new administrative machinery proposed in the Report.

ment in London are relieved in Poor-law institutions, whereas less than one-half are so relieved outside London. Notwithstanding the large number of medical charities in London, the London proportions for indoor and outdoor paupers under medical treatment are higher than the provincial proportions, and it appears that the young and middle-aged avail themselves of the London Poor-law infirmaries to an extent which, when compared with other parts of the country, is abnormal. The Commissioners note that there has been no reduction in pauperism notwithstanding sanitary improvements, and arrive at the following general conclusion:

"It is very unpleasant to record that, notwithstanding our assumed moral and material progress, and notwithstanding the enormous annual expenditure, amounting to nearly 60 millions a year, upon poor relief, education, and public health, we still have a vast army of persons quartered upon us unable to support themselves, and an army which in numbers has recently shown signs of increase rather than decrease. To what is the retrogression due? It cannot be attributed to lack of expenditure. Is this costly and elaborate machinery we have established defective, and if so where does it fail to accomplish its end? Is the material upon which this machinery operates becoming less amenable to the remedies applied?"

PART III.—HISTORICAL SKETCH OF THE POOR LAWS DOWN TO 1834.

This section of the report goes back to a period antecedent to the Elizabethan Poor Relief Act (1601); sketches the history of legislation in the eighteenth century; gives an account of the Poor Law Commission of 1832, and of the principles of the Poor Law Amendment Act of 1834, and concludes with a brief summary in which it is stated that the two main principles of the Poor-law reform of 1834, so far as relief was concerned, applied to the able-bodied alone; they were:

First.—That relief should not be offered to able-bodied persons and their families otherwise than in a well-regulated workhouse.

Secondly.—That the lot of the able-bodied should be made less eligible than that of the independent labourer outside.

PART IV.—HISTORICAL DEVELOPMENT AND PRESENT CON- DITION OF THE VARIOUS BRANCHES OF THE POOR LAW.

This part, which occupies 150 pages, contains, in addition to the recommendations with regard to the Local Government Board, the following proposal to substitute the term Public Assistance for Poor Law:

"It has been impressed upon us in the course of our inquiry that the name Poor Law has gathered about it associations of harshness, and still more of hopelessness, which we fear might seriously obstruct the reforms which we desire to see initiated. We are aware that a mere change of name will not prevent the old associations from recurring if it does not represent an essential change in the spirit of the work, but in our subsequent criticism and recommendations we hope to show the way to a system of help which will be better expressed by the title of Public Assistance than by that of Poor Law. The general aim will remain, as it always has been, the independence and welfare of the people, but as a means towards that end we desire to introduce into all branches of the work a spirit of efficiency and hopefulness. We think that this object will be made more easy of attainment, and that the work will be more accurately described by a change of title. Accordingly, we recommend that the Division of the Local Government Board which has hitherto dealt with 'the Relief of the Poor,' should in future be known as the Public Assistance Division."

As a corollary the Commissioners (in Part IX) recommend that the duties now performed by boards of guardians should be separated into two categories, and propose to call into existence two bodies for the discharge of the two sets of functions—namely:

(1) A local authority for central administration and control within an enlarged area.

(2) Local committees for dealing with applications, investigating and supervising cases, and undertaking such other duties as may be delegated by the local authority.

They recommend that the new local authority shall be known as the Public Assistance Authority, and that the committees which will carry on its work locally shall be known as Public Assistance Committees.

This part of the report concludes with the observation that, while the rise in Poor-law expenditure was accompanied by a diminution in pauperism, it was possible to regard it with some degree of acquiescence, since it is worth while to pay highly for the restoration of paupers to independence. There are, however, indications that the present administration has reached the limits of its remedial powers, and the Commissioners are convinced that its policy both of cure and of prevention must be extended more especially in making the giving of relief conditional upon the recipient accepting a way of life likely to restore him to independence. This, they point out, is no new principle. "It was the leading note of the 1834 administration, and has been so ever since, that one class—the able-bodied—should be relieved only under certain conditions. It is now necessary to apply the principle to other classes. It has proved, indeed, impossible to push a curative policy any further in its absence: sickness cannot be cured, either in institutions or at home, unless the patient will accept conditions; economic evils cannot be combated unless those who suffer from them will conform to conditions; moral weakness cannot be strengthened unless the authorities have power to impose conditions. And what those conditions are to be must become manifest through a careful and progressive study of the causes of pauperism."

PART V.—MEDICAL RELIEF.

This part of the report contains seventy pages, divided into three chapters, dealing respectively with the development of the system of medical assistance to the poor, a review of the system of medical assistance to the poor, and with general conclusions and proposals.

The third chapter begins with the following general statement:

The effects of a system of medical relief under the Poor Laws on a principle of restriction, hedged in by difficulties of attainment, and, till lately, accompanied by political disfranchisement, have been clearly shown in the evidence given before us:

1. It has to some extent produced the result which was intended. It has deterred men from applying to the Poor Law, has fostered independence, has called into existence and stimulated the growth of friendly societies, medical clubs, provident dispensaries, and the like.

2. It has, however, probably led to the neglect on the part of many to provide themselves, their wives, and families with medical attendance, and so helped to impair the health of the present generation.

3. It has called into existence a vast amount of medical charity. The out-patient wards of hospitals are only one instance of the eagerness with which men avail themselves of free medical advice, often, no doubt, as a second opinion where there is grave apprehension or want of confidence in a medical man.

4. It has helped to develop on a large scale the sale of patent medicines, and has created a class of practitioners who give advice and supply medicines at an almost inconceivably low price. As to the value of that advice or of those medicines, we pronounce no opinion. In matters of health the lessons of experience are learnt but slowly and sometimes too late to profit the learner, and it may be said that the system tends to encourage inefficiency and to demoralize both him who gives and him who takes.

The first point to which we would call special attention is the large number of institutions and of social agencies dealing with sickness. We have hospitals, convalescent homes, and retreats for the dying, maintained by voluntary effort. We have infirmaries under the care of the guardians, and infectious hospitals, managed by the sanitary authorities. All these provide institutional treatment. For domiciliary treatment, we have outdoor medical relief from the Poor Law, provident dispensaries, and free dispensaries. We have also a far-reaching organization of friendly societies which put medical aid in the forefront of their pro-

gramme and which are of great value to the nation because not only do they aid the growth of thrifty and provident habits, but they give an opportunity for the exercise of self-government. As things stand, we have not merely much overlapping and consequent waste, but the illogical result that, whereas the inmate of a workhouse infirmary runs the risk of disfranchisement, the patient in a voluntary hospital incurs no such liability.

Sickness as a Cause of Pauperism.

The Commissioners then proceed to consider reforms for the co-ordination, utilization, and development of existing agencies for the provision of medical assistance. They state that sickness is admittedly one of the chief causes of pauperism, and that the more chronic its character and the longer its duration, the greater the likelihood of its producing dependence upon the rates. They estimate that at least one-half of the total cost of pauperism is swallowed up in direct dealing with sickness, while to this burden must be added its indirect effects, the widows, children, and old people cast upon the rates through preventable deaths of breadwinners, and the host of degenerate, imbecile, maimed, and blind, with whom disease helps to populate our workhouses. They conclude that there is little, if any, exaggeration in the statement that "to the extent to which we can eliminate or diminish sickness among the poor, we shall eliminate or diminish one-half the existing amount of pauperism."

Gratuitous Medical Attendance.

Considering next objections to gratuitous medical attendance, the Commissioners conclude that while one of the first objects of a change in the present system of medical assistance should be to render it more accessible to, and more readily obtainable by, the working classes, it should be administered in such a way that those who contribute towards their own medical assistance should obtain it on more eligible terms than those who do not.

Objections to Transfer of Medical Assistance to Sanitary Authorities.

The report states that numerous witnesses, a considerable proportion of whom were medical officers of health, suggested that the proper remedy for the existing chaos in the organization of medical assistance of the poor is to hand over the administration of medical assistance to the sanitary authority, thus uniting in one body the responsibility for the public prevention and treatment of disease.

The majority of the Commissioners reject this proposal on various grounds. Among others that it is the duty of the sanitary authority by propaganda, persuasion, and forethought, to make its services attractive to all classes of the community, independent of their economic position; that these authorities have allowed to fall into desuetude the power of recovering the cost of treatment in their hospitals, which, except in London, they legally possess; that while there are over 1,800 sanitary authorities in England and Wales, there are only 643 Poor Law unions, so that to hand over medical assistance to the sanitary authorities would be to hand it over to a larger number of authorities with smaller areas than at present, thus reverting to a system that existed prior to 1834; that as medical treatment is largely a question of dieting, the transfer would involve extending the functions of sanitary authorities to maintenance, thus creating two relief authorities where only one exists at present; and, finally, that before the functions of an existing authority are enlarged by transferring to it the duties of another, it is generally required that the authority so enlarged or elevated shall have discharged satisfactorily the primary duties entrusted to it. "This," the Commissioners state, "cannot be said of many sanitary authorities, especially in rural districts."

After analysing further the defects of the present system in quality, in extent, and from overlapping, the Commissioners propound the following scheme of reform, which is quoted in full:

"(f) SCHEME OF REFORM.

"It is in the hope of attaining this end that we submit the following scheme of reform which assumes that the area of administration of the future Public Assistance Authority will be the county and the county borough, and that within each area this authority will have local committees working under it.

General.

"1. That medical assistance should be reorganized on a provident basis."

"2. That in certain cases power of compulsory removal to and detention in an institution should be given to the authorities under proper safeguards.

"3. That there should be systematic co-operation between the Public Assistance Authorities, the Sanitary Authorities, the Education Authorities, and the Voluntary Medical Institutions, based on a clear definition of their respective functions.

"4. That no disfranchisement should be attached to any form of medical assistance.

"5. That the arrangements for indoor and outdoor medical assistance should be periodically inspected by medical inspectors on behalf of the Local Government Board.

Functions of the Public Assistance Authority as to Medical Assistance.

"6. That in taking over the existing powers and duties of boards of guardians in regard to medical relief the new Poor-law authority, or, as we shall call it, the Public Assistance Authority, shall undertake the following functions:

"(i) To co-ordinate and, when necessary, supplement the medical institutions of the county or county borough and to suggest methods of co-operation with the sanitary authorities and the authorities in charge of voluntary hospitals.

"(ii) To organize an outdoor and provident medical service easily accessible in all parts of the county or county borough, this service to include the provision of competent midwives.

"(iii) To develop an adequate nursing service throughout the county or county borough, preferably in connexion with voluntary nursing associations.

"(iv) To subscribe, when necessary, towards these purposes.

"(v) To arrange for adequate supervision of, and report on the efficiency and adequacy of the medical institutions and medical service through the county or county borough.

Establishment of Medical Assistance Committees.

"7. That, to assist the Public Assistance Authority in carrying out the above functions, they shall appoint a committee from among their number, to which shall be added representatives of the Health Committee of the County Council or of the County Borough Council, and of the local branch or branches of the British Medical Association. This committee shall be called the County or County Borough Medical Assistance Committee, as the case may be, and shall have power to co-opt representatives of local hospitals, county or county borough nursing associations, dispensaries, and registered friendly societies.

"8. That, where necessary, a local committee on similar lines shall be appointed by each Public Assistance Committee for the purposes of the local administration of medical assistance. This committee shall be termed the Local Medical Assistance Committee.

"9. That all, or any, of the functions defined in No. 6 may be referred by the Public Assistance Authority to the County or County Borough Medical Assistance Committee.

"10. That the following shall be the lines of procedure for carrying out the functions mentioned in No. 6:

Institutions.

"(i) To consider in conjunction with each "Local Medical Assistance Committee" the needs of the county or county borough and the needs of each relief district in the way of hospital (including infirmary) accommodation.

"(ii) To reorganize existing Poor-law medical institutions throughout the county, or county borough, with a view to making them most effective for different classes of patients. (This would be done in conjunction with the committees in charge of workhouses, schools, etc.)

"(iii) To organize schemes of co-operation between Public Assistance institutions and voluntary hospitals.

²Cf. Report by Dr. McVail, pp. 157-162; Report of Committee of British Medical Association on Contract Practice; Evidence by Dr. Lauriston Shaw etc.

"(iv) To develop a system of paying and free cottage hospitals in conjunction with voluntary and endowed charities, these to include provision for confinement cases.³

"(v) To arrange schemes of co-operation between hospitals and provident dispensaries or outdoor medical service.⁴

Outdoor Medical Service.

"(i) To require the 'Local Medical Assistance Committee,' in conjunction with the local doctor, to map out their district into convenient medical districts or 'dispensary areas.'⁵

"(ii) To approach any free or provident medical institution, including private medical clubs, already existing in the district, and invite them to fall in with the scheme. (Refusal not to check procedure.)⁶

"(iii) The local authority may subscribe to the provident dispensaries, subject to the sanction of the Local Government Board, and under the conditions mentioned in Section 10 of the Poor Law Act, 1879.

Relation of the Poor Law to Provident Dispensaries.

"11. That where any applicant for medical assistance is not a member of a provident society, he shall apply to and at once be treated by a district medical officer.⁷

"12. That the relieving officer, or, as he will be called in future, the Assistance Officer, shall inquire into and report the case to the Public Assistance Committee, whose action shall be directed towards—

(i) Recovery of cost.

(ii) Strengthening of provident agencies.

"13. That with a view to enlisting the services of all competent medical practitioners in the locality of a provident dispensary, the British Medical Association be requested to suggest a general scheme or scale of fees and wage limit to be applied by their local branches as local circumstances may suggest.

"14. That under such scheme all local medical practitioners consenting to come under it shall be on the list

³ It is not suggested that this should be done suddenly or that it should be thrown mainly upon the rates. It is a popular form of charity, and to publish the needs of a district would be a guide to charitable donors. Also there is much evidence in favour of small self-supporting hospitals, or nursing homes, and these might be organised in conjunction with the local medical men, and, to some extent, upon a provident basis.

⁴ This scheme would have to vary with local conditions. In London the Central Hospitals Council and the Hospitals Committee of the British Medical Association are in favour of pre-arranged treatment to dispensary members who may be sent for consultation by dispensary doctors, and of using the out-patient departments of the hospitals mainly for consultative purposes. (Cf. Holland, Vol. III., App. xvii. (B), and Montefiore, Vol. III., App. xxii. (A).) We have no evidence to show whether provident hospitals would follow the same line, but at Manchester the hospital authorities refer out-patients to the provident dispensary. The British Medical Association witnesses say: "It is remarkable how many hospitals who only give general replies on other matters go out of their way to say that they would welcome co-ordination of the provident dispensaries." (Whitaker, 39191.)

⁵ The nature of the "dispensary" to be established in each area would vary with the nature of the district. In large and sparsely-populated districts a room in a cottage, with a locked cupboard for drugs, might be sufficient. In a crowded area, a complete building, with waiting rooms, etc., and a dispenser, might be necessary; while in medium districts attendance at the doctor's own house might be preferred. The determining factor would be the distance to be travelled by the patient. Existing buildings might often be utilized, e.g., public assistance, provident, and free dispensaries.

⁶ It is probable that in many cases these would join at once. The Secretary to the Metropolitan Provident Medical Association says that already some of the free dispensaries have been converted into provident dispensaries, and that he is constantly approached by others with the same object. (Cf. Warren, 35487 (44), 35592-4.) Want of funds is generally the chief obstacle to the establishment of a universal provident system; this motive would probably increase. The head of a large free dispensary in Birmingham is strongly in favour of a provident system. (Cf. Evidence of Dr. Haeger Wilson, 44618 et seq.) Doctors also are glad to come in with their private patients, thus saving themselves the trouble of management and collection, and friendly societies arrange for their members to join.

⁷ This procedure may be slightly modified if, and when, the office of District Medical Officer is abolished. On this matter the Commissioners say: "When the scheme which we propose is in full working order, the member of a provident dispensary will be able to choose his doctor from the list of those working with the dispensary. We recommend that certain cases in receipt of public assistance, such as the aged and widows with young children, might be enrolled as members, and their fees paid by the Public Assistance Committee. To ensure prompt attendance in cases of sudden and urgent necessity, we think that every doctor who joins the dispensary should be required to give an undertaking to attend any such case for a suitable fee. We hope that, ultimately, it may be possible to dispense altogether with the service of the district medical officer, and that his duties will be shared among medical men practising in the district. Meanwhile, arrangements might be made to retain the district medical officer on the staff of the provident dispensary."

of dispensary doctors, and any applicant who is a member of the dispensary shall be entitled to select such a practitioner as he may prefer.

"15. That arrangements should be made, where necessary, for the reception of patients in voluntary and general hospitals by the payment of their cost or by some other agreement between the Public Assistance Committee and those in management of the hospital.

"16. That any practitioner attached to a provident dispensary may, where the patient is a member of such dispensary and in need of institutional treatment, recommend him for admission to the local Public Assistance infirmary, and in certain cases, where arrangements have been made, to a voluntary or general hospital.

"17. That, so far as the patient is concerned, admission under such conditions shall be covered by the subscription to the provident dispensary.

"18. That as regards certain cases in receipt of public assistance (such as the aged and widows with young children), the Public Assistance Committee may enrol all such cases as members of a provident dispensary by paying the necessary fees."

METHODS OF ASSISTANCE.

Indoor Relief or Institutional Assistance.

The Majority Report recommends that general work-houses should be abolished, and advises classification as an essential preliminary to making indoor relief rightly effective, and accordingly that such relief should be given in separate institutions appropriate to the following classes of applicants:

1. Children.
2. Aged and infirm.
3. Sick.
4. Able-bodied men.
5. Able-bodied women.
6. Vagrants.
7. Feeble-minded and epileptics.

It is recommended that the treatment of inmates should be made as far as possible curative and restorative; that all indoor cases should be revised from time to time by a responsible committee with a view to seeing whether the existing treatment is producing the desired result, or whether it is desirable that the treatment should be altered. It is also recommended that the central authority should exercise a more strict control over expenditure on buildings and equipment.

MEDICAL RELIEF AND ASSISTANCE.

The main proposals of the Majority Report for medical assistance are as follows:

Medical Relief or Assistance.

"The primary responsibility of the Public Assistance Authorities for the inspection and supervision of medical assistance should be clearly recognized and carefully maintained; but, meanwhile, the arrangements for both indoor and outdoor medical assistance should be periodically inspected by medical inspectors on behalf of the Local Government Board; to this end the Board's staff of medical inspectors should be increased. (V., 127.)

"That, the Public Assistance Authority, to assist them in carrying out the functions in connexion with medical assistance, shall appoint a committee from among their number, to which shall be added representatives of the Health Committee of the County Council, or of the County Borough Council, and of the local branch or branches of the British Medical Association. This committee shall be called the County or County Borough Medical Assistance Committee, as the case may be, and shall have power to co-opt representatives of local hospitals, county or county borough nursing associations, dispensaries, and registered friendly societies.

"That where necessary a local committee on similar lines shall be appointed by each Public Assistance Committee for the purposes of the local administration of medical assistance. This committee shall be termed the Local Medical Assistance Committee.

"That all or any of the functions of the Public Assistance Authority in regard to medical assistance may be referred to the County or County Borough Medical Assistance Committee.

"That, in all matters affecting medical assistance, there should be systematic co-operation between the Public Assistance Authorities, the Public Health Authorities, the Education Authorities, and the Voluntary Medical Institutions, based on a clear definition of their respective functions.

"That the medical and nursing needs of each area, whether institutional or otherwise, be reviewed, and, if necessary, supplemented, regard being had to the available provision made by Poor-law, sanitary, or voluntary authorities.

"That medical assistance should be organized on a provident basis.

"That a general system of provident dispensaries should be established, of which existing voluntary outdoor medical organizations be invited to form an integral part, and that every inducement should be offered to the working classes below a certain wage limit to become, or to continue to be, members of a provident dispensary. To this end the subscription to the provident dispensary should cover the following advantages to its members:

(a) Power to choose their own doctor from the doctors upon the list of the dispensary.

(b) The provision of adequate medical assistance at a rate or fee within the reach of those subscribing to the provident dispensary.

(c) Institutional treatment upon a recommendation from the dispensary doctor.

"That the Public Assistance Authority should have power to subscribe, if necessary, to the purposes indicated in Recommendations 114, 115, and 116.

"That medical treatment should be more readily accessible to all who are in need of it; that, in cases of illness in which immediate treatment is necessary, the physical condition of the patient should be the first consideration; that in such cases medical aid should be obtainable in the first instance by application to any medical officer in the service of the provident dispensary.

"That, except as regards the cases requiring immediate attention above referred to, all necessitous persons shall receive medical relief through the Public Assistance Committee.

"That certain cases in receipt of Public Assistance, such as the aged and widows with young children, might be made members of the provident dispensary on payment of the necessary fees by the Public Assistance Committee.

"That domiciliary medical assistance at the public cost should be conditional upon the maintenance of a healthy domicile and good habits.

"That no disfranchisement should be attached to any form of medical assistance."

MINORITY REPORT.

The Minority Report is signed by the Rev. Prebendary H. Russell Wakefield, Alderman and ex-Mayor of the Borough of Marylebone and Chairman of the Central Unemployed Body for London; Mr. Francis Chandler, Secretary to the Amalgamated Society of Carpenters and Joiners and ex-Chairman of Chorlton Board of Guardians; Mr. George Lansbury, member of the Borough Council and Board of Guardians, Poplar, and of the Central Unemployed Body for London; and Mrs. Sidney Webb.

It agrees with the Majority Report on many matters of principle.

It recommends the abolition of Boards of Guardians and the transference of their duty and property to the County and County Borough Councils strengthened for the purpose, which should act as Destitution Authorities according to the following plan, which is quoted in full:

"That the services at present administered by the Destitution Authorities (other than those connected with vagrants or the able-bodied)—that is to say, the provision for:—

(i) Children of school age;

(ii) The sick and the permanently incapacitated, the infants under school age, and the aged needing institutional care;

(iii) The mentally defective of all grades and all ages; and

(iv) The aged to whom pensions are awarded—should be assumed, under the directions of the County and County Borough Councils, by

- (i) The Education Committee;
- (ii) The Health Committee;
- (iii) The Asylums Committee; and
- (iv) The Pension Committee respectively."

It recommends also that the general mixed workhouse should be abolished, and replaced by a system of classification and special treatment adapted to the requirements in accordance with the scheme outlined above.

MEDICAL RELIEF.

With regard to the Poor Law Medical Service and medical relief generally, the minority of the Commissioners report as follows:

"That the continued existence of two separate rate-supported medical services in all parts of the kingdom, costing, in the aggregate, six or seven millions sterling annually—overlapping, unco-ordinated with each other and sometimes actually conflicting with each other's work—cannot be justified.

"That the very principle of the Poor Law Medical Service—its restriction to persons who prove themselves to be destitute—involves delay and reluctance in the application of the sick person for treatment; hesitation and delay in beginning the treatment; and, in strictly administered districts, actual refusal of all treatment to persons who are in need of it, but who can manage to pay for some cheap substitute. These defects, which we regard as inherent in any medical service administered by a Destitution Authority, stand in the way of the discovery and early treatment of incipient disease, and accordingly deprive the medical treatment of most of its value.

"That it has been demonstrated to us beyond all dispute that the deterrent aspect which the medical branch of the Poor Law acquires through its association with the Destitution Authority causes, merely by preventing prompt and early application by the sick poor for medical treatment, an untold amount of aggravation of disease, personal suffering, and reduction the wealth-producing power of the manual working class.

"That the operations of the Poor Law Medical Service, being controlled by Destitution Authorities and administered by Destitution Officers, inevitably take on the character of unconditional 'medical relief'—that is, relief of the real or fancied painful symptoms—as distinguished from remedial changes of regimen and removal of injurious conditions, upon which any really curative treatment, or any effective prevention of the spread or recurrence of disease, is nowadays recognized to depend.

"That whilst domiciliary treatment of the sick poor is appropriate in many cases, it ought to be withheld—

(i) Where proper treatment in the home is impracticable;

(ii) Where the patient persistently malingers or refuses to conform to the prescribed regimen; or

(iii) Where the patient is a source of danger to others.

"It has become imperative in the public interest that there should be, for extreme cases, powers of compulsory removal to a proper place of treatment. Such powers cannot, and in our opinion should not, be granted to a Destitution Authority.

"That where Destitution Authorities cease to abide by the limitation of their work to persons really destitute, or pass beyond the dole of 'medical relief,' their attempt to extend the range or improve the quality of the Poor Law Medical Service brings new perils. We cannot regard with favour any action which, in order to promote treatment, openly or tacitly invites people voluntarily to range themselves among the destitute; or which tempts them, by the prospect of getting costly and specialized forms of treatment, to simulate destitution. Nor do we think that an authority charged with the relief of destitution, whatever its method of appointment or whatever the area over which it acts, or any authority acting through officers concerned with such relief, whatever their official designation, can ever administer a Medical Service with efficiency and economy.

"That, with regard to the suggestion that the medical treatment of the sick poor should be left either to provident medical insurance or to voluntary charity, it has been demonstrated to us that these offer no possible alternative to the provision for the

sick made by the Public Authority. With regard to domiciliary treatment, the evidence as to medical clubs "contract practice," provident dispensaries, and the out-patients' departments of hospitals is such as to make it impossible to recommend, in their favour, any restriction of the services at present afforded by the district medical officers and Poor-law dispensaries. Nor do we feel warranted in giving any support to the proposal made to us that the whole of this outdoor medical service of the Poor Law should be superseded by a publicly subsidized system of letting the poor choose their own doctors. Any such system would, in our judgement, lead to an extravagant expenditure of public funds on popular remedies and "medical extras," without obtaining, in return for this enlarged 'Medical Relief,' general regularity of life or more hygienic habits in the patient. With regard to institutional treatment, we gladly recognize the inestimable services rendered to the sick poor by the hospitals, sanatoriums, and convalescent homes supported by endowments or voluntary contributions. We approve of the use now made of these institutions by public authorities, and we think that many more suitable cases than at present might, on proper arrangements as to payment, be transferred from rate-maintained to voluntary institutions. But it is clear that such institutions provide only for a small fraction of the need, and that they leave untouched whole districts for some cases, and whole classes of cases everywhere, which there is no prospect of their being able or willing to undertake.

"That the Medical Service of the Public Health Authorities, which now extensively treats disease, and actually maintains out of the rates a steadily increasing number of the sick poor, is based on principles more suited to a State Medical Service than that of the Poor Law. These principles, which lead, in practice as well as in theory, to searching out disease, securing the earliest possible diagnosis, taking hold of the incipient case, removing injurious conditions, applying specialized treatment, enforcing healthy surroundings and personal hygiene, and aiming always at preventing either recurrence or spread of disease—in contrast to the mere 'relief' of the individual—furnish in fact the only proper basis for the expenditure of public money on a Medical Service.

"That such compulsory powers of removal in extreme cases, as have been asked for, are analogous to those already exercised, with full public approval, by the Public Health Authorities; and that the proposed extension of such powers can properly be granted only to an authority proceeding on Public Health lines.

"That we therefore agree with the responsible heads of all the four Medical Departments concerned—the Chief Medical Officer of the Local Government Board for England and Wales, the Medical Member of the Local Government Board for Scotland, the Medical Commissioner of the Local Government Board for Ireland, and the Medical Officer of the Board of Education—in ascribing the defects of the existing arrangements fundamentally to the lack of a unified Medical Service based on Public Health principles.

"That in such a unified Medical Service, organized in districts of suitable extent, the existing medical officers of health, hospital superintendents, school doctors,* district

medical officers, workhouse and dispensary doctors, and medical superintendents of Poor-law infirmaries—the clinicians as well as the sanitarians—would all find appropriate spheres; that one among them being placed in administrative control who has developed most administrative capacity.

"That we do not agree with the suggestion that the establishment of a unified Medical Service on Public Health lines necessarily involves the gratuitous provision of medical treatment to all applicants. It is clear that, in the public interest, neither the promptitude nor the efficiency of the medical treatment must be in any way limited by considerations of whether the patient can or should repay its cost. But we see no reason why Parliament should not embody in a clear and consistent code definite rules of chargeability, either relating to the treatment of all diseases, or of all but those specifically named; and of the recovery of the charge thus made from all patients who are able to pay."

UNEMPLOYMENT.

Proposed Ministry of Labour.

The Minority Report discusses at length the question of unemployment and its prevention, and recommends the establishment of a Ministry of Labour with six Divisions, one being a National Labour Exchange, the function of which should be not only (a) to ascertain and report the surplus or shortage of labour of particular kinds, at particular places; and (b) to diminish the time and energy now spent in looking for work, and the consequent "leakage" between jobs; but also (c) so to "dovetail" casual and seasonal employments as to arrange for practical continuity of work to those now chronically under-employed.

For the ultimate residuum of men in distress from want of employment, who may be expected to remain, after the measures they recommend have been put in operation, the minority of the Commissioners suggest that maintenance should be freely provided, without disfranchisement, on condition that they submit themselves to the physical and mental training that they may prove to require. That it should be the function of the Maintenance and Training Division of the Ministry of Labour to establish and maintain receiving offices in the various centres of population, at which able-bodied men in distress could apply for assistance, and at which they would be medically examined and have their faculties tested in order to discover in what way they could be improved by training. They would then be assigned either to suitable day training depôts or residential farm colonies, where their whole working time would be absorbed in such varied beneficial training of body and mind as they proved capable of; their wives and families being, meanwhile, provided with adequate home aliment.

LITERARY NOTES.

A CORRESPONDENT raises a question of quantity in regard to the pronunciation of the word "vertigo." He says he has been taken to task for pronouncing it with the middle syllable long. There is no question that the *i* in vertigo is long in Latin. But English lexicographic oracles offer a choice. The *Encyclopædic (Lloyd)* and the *Standard Dictionaries (Funk and Wagnall)* give both pronunciations, the former putting vertigo first, the latter giving the preference to vertigo. We ourselves share that preference. It has the sanction of Swift, who was very strict in his prosody, and who writes in the lines about his own death (Sir Walter Scott's edition):

That old vertigo in his head
Will never leave him till he's dead.

Charles Lamb, too, writes:

This sick vertigo here
Preacheth of temperance, etc.

In both these cases the rules of scansion require vertigo. On the other hand, there is the "genius of the English language" which tends to throw the accent as far back as possible. Therefore, if any one chooses to pronounce the word vertigo, we should say with Dogberry, "Take no note of him, but let him go." We may quote, in illustration of the freedom which we think Englishmen should allow each other in matters of pronunciation—in accordance

* The question has been raised of the relation in which, with a unified Medical Service, the necessary medical activities of the Local Education Authorities should be placed. The question is one to be determined, in our opinion, by the dominant characteristics of the service. Within the limits of school age, the predominant service should be that of education; and the responsibility for the normal child should rest with the Local Education Authority. The case is different with the mentally defective child, for which the new Local Authority for the Mentally Defective will have the responsibility; and with the child withdrawn from school for definite illness, for which the Local Health Authority will be responsible. But when the child, without being so ill as to be withdrawn from school, requires the services of a doctor—as, for instance, in school medical inspection, in medical examination for scholarships, and in the treatment of minor ailments—we suggest, that the Local Education Authority should, where the two Authorities are Committees of the same Council, not set up a medical staff of its own, but call in the Local Health Authorities as its agent; just as it does already with regard to inspecting and certifying the drainage of the school building. On the other hand, where the children in the hospitals and sanatoria of the Local Health Authority are in need of education (a point now often neglected, we suggest that the Local Health Authority should not have its own teachers, but should call in the Local Education Authority as its agent. The case may be different where (as at present in England and Wales, outside the County Boroughs) the two Authorities are not Committees of the same Council, and do not serve the same areas. But even here arrangements could usually be made on similar lines.

with the practice of painters and poets, as laid down by Horace, *Hanc veniam petimusque damusque vicissim*—a story which, though old, is worth repeating. It was in the days when every professional man was supposed to have the classics at his finger ends, and, as Sidney Smith said, a false quantity perpetrated early in life often ruined a promising career. A Scottish advocate was pleading before the House of Lords, and repeatedly spoke of curators. We think it was Lord Denman whose feelings were so ruffled by this pronunciation that at last he asked the learned counsel if curator would not better grace his eloquent lips. The barrister at once retorted, "Certainly, my lords. In the presence of so many eminent senators and illustrious orators, I have not the slightest hesitation in speaking of curators." Coming back to our correspondent's question, we are inclined to say that among medical men vertigo is the generally accepted pronunciation.

Shiute (Health) is the name of a new monthly journal devoted to the diffusion of a knowledge of health and hygiene. It is to be the official organ of the Women's National Health Association, and it will appear under the editorship of the Countess of Aberdeen. It is intended to make the magazine thoroughly adapted to the needs of the Irish people, and the prevailing maladies and exceptional conditions of the country will be fully dealt with. The first number will contain a foreword and notes by the editor; an article on the results obtained in the home treatment of tuberculosis by the class method, by Joseph Pratt, M.D., of Boston, U.S.A., with photographs illustrating how sleeping places were contrived for patients on the roofs and in the yards of tenement dwellings; an article on what the Women's National Health Association can do to advance the cause of school hygiene, by T. Clarke, LL.D.; an account of the babies' clubs of Belfast; and a short story. In addition to the articles and notes, each number will form a record of work done by including the reports of the various branches of the association. The publishers are Messrs. Maunsell and Co., 96, Middle Abbey Street, Dublin.

"The Mosaic Sanitary Code and its Relation to Modern Sanitation" was, we learn from the *Yorkshire Daily Observer*, the subject of a highly interesting and valuable paper read by Mr. P. M. Raskin, of Leeds, before a general meeting of the North-East Centre of the Sanitary Inspectors' Association. Mr. Raskin said there was not a distinct department of public health in the government of ancient Judea. The duty of dealing with infectious disease, such as leprosy and epidemics of all kinds, was delegated to the priests. The Talmud mentioned the office of a physician in the Temple, whose duty it was to look after the health of the High Priest. In later times, however, according to the Talmud, every town counted among its permanent officials a physician who supervised the circumcision of children and looked after the communal well-being. A theological student was even forbidden to live in a place where there was no physician. The main provisions of the Mosaic sanitary law related to (1) the prevention of infectious disease; (2) food and diet; (3) sewage and refuse disposal; and (4) domestic sanitation, ablutions, baths, and general cleanliness. The laws with reference to infectious disease, as laid down in Leviticus and Numbers, seemed to be based on the principle that as infectious diseases were mostly communicated by contact, all cases of such were to be isolated; that all contact with any centre of infection was to be avoided; that when such contact, in unavoidable circumstances, had taken place, there must be first segregation to prevent the spread of infection, and finally purification before the infected person could be readmitted into society. The great scourge in many parts of the East, as Egypt, Arabia, etc., still was leprosy. The Mosaic laws, therefore, lay down stringent rules for preventing the spread of the terrible malady. Infected clothing was to be burnt, an infected house had to be emptied, the infected parts of the building removed, and the walls scraped. If the malady recurred, the whole house had to be demolished and the materials removed to an unclean place outside the camp, and never used again. The priest, who seemed to have acted as medical officer of health and sanitary inspector combined, had to diagnose every suspicious case and to visit infected houses, and then finally declare them clean or unclean. Every corpse

was considered a possible centre of infection, and those who touched a corpse, or were under the same roof as a corpse, or who touched a grave, were regarded as unclean, and had to purify themselves. Modern sanitarians, said Mr. Raskin, might prefer to disinfect a house with carbolic acid, sulphur, or formalin than with the Biblical caper-bush hyssop, but this possessed great disinfecting properties and was very likely the best disinfectant of the time. The laws as to food might also be classed under the head of sanitary laws, for they might be fairly considered to have been ordained in the interests of health, moral and physical. The prohibition against eating blood, repeated in the Pentateuch not less than five times, exclusively belonged to the Mosaic law, and must have been made on sanitary grounds, both in the immediate and wider sense of the term. The immediate reason for this prohibition was probably because blood was considered the likeliest vehicle for the entrance of the germs of disease into the human system. The farther command to cover all blood with earth (to disinfect it) lent additional ground to the supposition that blood was considered unclean from a sanitary point of view. Passing to the provisions made by Moses for the disposal of sewage and refuse, Mr. Raskin said he believed there was no direct indication in the Pentateuch about the method in vogue in ancient Judea for the disposal of such matter. But according to Josephus Flavius, who wrote about 75 A.D. and a later Biblical commentator, David Kimbi, perpetual fires were kept up outside the gates of Jerusalem for the purpose of consuming the refuse of the city. If this were the case, then the problem of refuse disposal must have been solved in ancient Judea in as efficient a manner as in our own time. In the ancient Judean Public Health Act of about 450 B.C., provision was also made for dealing with offensive trades. The Talmudists regarded the laws of health as of greater importance than those which were of a merely ritualistic character. It was forbidden to eat the meat of an animal that had eaten poison, or to drink water left uncovered overnight. Coins were not to be placed in the mouth, as they might have been touched by persons suffering from infectious disease. It was likewise forbidden to eat from unclean vessels, or from vessels that had been used for unseemly purposes, or to eat with dirty hands. The washing of the hands and face in the morning was considered very important. There was also the custom of washing the hands before and after meals. Mr. Prigdin Teale, who was in the chair, said the paper was one of the most remarkable and interesting the association had had addressed to them. He had given a short account of the discovery in Crete of terra-cotta pipes for carrying water in a house and the period must have been about 2000 B.C. And it seemed that from that remote age until seventy or eighty years ago civilization had not been in the habit of using terra-cotta either for water carriage or drainage. It must have been the adherence of the Jewish community to the rules laid down in the ancient code which had given them their wonderful vitality. He had often wondered, when an ancient Jewish community grew to such a size that it was difficult to carry out all the details of the code, if provision were made for emigration. Nearly every one of the greatest cities of antiquity had disappeared, and he had had the impression that such places as Babylon and Nineveh had grown to such a size that in the end the sanitary arrangements could not be carried out, and thus the sites had become unhealthy and destructive to life.

SOUTHWOLD LIBEL CASE.

THE following additional donations have been promised to the fund opened to assist Drs. Mullock and Tripp in defraying the heavy expenses which they incurred as the result of the recent action which they were called upon to defend:

	£	s.	d.
Dr. S. Johnson Taylor (Norwich)	5	5	0
Anonymous	4	4	0
Anonymous	2	2	0

Cheques should be made payable to Dr. H. P. Helsham, Beccles, or to Dr. W. Tyson, Lowestoft.

Medical News.

THE eighth International Congress of Otolaryngology will be held at Buda-Pesth next August.

DR. SCHUMANN LECLERCQ, of Carlsbad, has been made Chevalier of the French Legion d'Honneur.

THE annual general meeting of the Association of Certificated Dispensers will be held in the Apothecaries' Hall, London, on Thursday next at 7.30 p.m.

AN association for the repression of venereal diseases has been founded at Warsaw. It comprises two sections: one social and legislative, the other medical.

A SUM of £1,080 has already been collected for the erection of a monument in memory of the late Professor Cornil. M. Fallières, President of the French Republic, has given £12 to the fund.

AT the January examination for sanitary inspectors under the Public Health (London) Act, 1891, held by the Sanitary Inspectors' Examination Board, 19 candidates passed, of whom 9 were women.

A GOVERNMENT Laboratory of Bacteriology has been founded in Warsaw. The director is Dr. Tschernomozky. The laboratory is intended chiefly for the purposes of veterinary and public health researches.

THE German Emperor has conferred upon Sir James Reid, Bart., Physician-in-Ordinary to the King and the Prince of Wales, the First Class of the Order of the Crown, on the occasion of the visit of their Britannic Majesties to Berlin.

THE Cross of a Commander of the Francis Joseph Order has been conferred upon Professor Koloman Mueller, of the Medical Faculty of the University of Buda-Pesth. Professor Mueller is a member of the Hungarian House of Magnates.

THE University of Heidelberg has received from a foreign benefactor interested in the advancement of science the sum of £5,500 towards the foundation of a radiographic institute. It is expected that the institute will be in working order by Easter.

DR. JAMES ROSS WATT, of Ayr, President of the Ayrshire Branch of the British Medical Association, has, on the recommendation of the Earl of Eglinton and Winton, Lord Lieutenant of the county, been appointed a Justice of the Peace for Ayrshire.

AT a conference on women's lodging houses to be held at the British Institute of Social Service, 11, Southampton Row, London, W.C., under the presidency of Sir John Kirk, Director of the Ragged School Union, on Wednesday next, at 4 p.m., it is proposed to form a small committee to consider how to forward the national provision of safe shelter for unprotected women.

WE learn from the *Boston Medical and Surgical Journal* that radium has been for the last five years in continuous use in a clinic at the Boston City Hospital. Although without the designation, a radium institute has in a way existed there, where questions relating to the physics of radium have been studied as a guide to the intelligent use of it in the treatment of the patients.

ON the occasion of their leaving Orsett, Dr. and Mrs. Corbett were presented by their friends with a handsome grandfather clock, an illuminated address, and a purse of 50 guineas, as a mark of respect. Dr. Corbett, in acknowledging the presentation, regretted that owing to bronchial attacks he had been recommended to leave Orsett, after residing there for seventy years, and take up his residence in a warmer place.

THE address by Sir Thomas Oliver on some medical and insurance problems arising out of recent industrial legislation, given before the Life Assurance Medical Officers' Association on November 4th, 1908, as reported in our columns of November 14th, page 1496, has been printed in a pamphlet, together with a report of the meeting on December 2nd, when the discussion of the paper was continued. Copies can be obtained on application to the honorary secretaries of the society (2, Frederick Place, Old Jewry, E.C.), price two shillings.

THE United States Senate on January 26th passed a bill forbidding the importation of opium into the States except for medicinal purposes, and then only under strict regulations to be prescribed by the Secretary of the Treasury. All other forms of opium, smoking opium, or any derivative of opium, are, according to the *Medical Record*, absolutely shut out. Possession of the forbidden drug, it is expressly stated, shall be deemed sufficient evidence to convict, and offenders may be punished with two years' imprisonment and a fine of £1,000.

THE fourth meeting of the Departmental Committee appointed by the Lord President of the Council to con-

sider the working of the Midwives Act was held on February 17th at the Privy Council Office, Mr. Almeric W. FitzRoy presiding. The following witnesses attended and gave evidence: Miss Wilson, President of the Incorporated Midwives Institute; Mr. F. B. Harris, Deputy Town Clerk of Nottingham, on behalf of the Association of Municipal Corporations; Mr. Joseph Brown, of Dewsbury, on behalf of the Association of Poor-law Unions in England and Wales; and Mrs. Wallace Bruce, on behalf of the Association for Promoting the Training and Supply of Midwives.

THE members of the West London Medico-Chirurgical Society dined together at the Hotel Great Central, Marylebone, on February 12th, with Colonel T. H. Hendley, I.M.S., in the chair. Mr. R. Lake proposed the toast of "The Imperial Forces" in a patriotic speech, which was acknowledged by Inspector-General J. Porter, R.N., who emphasized the importance of attracting the best men to the naval medical service, as it was necessary to keep the men in the Navy in health because they took so long to train that it was not an easy matter to replace them. Sir Richard Douglas Powell, in submitting the toast of "The West London Medico-Chirurgical Society," spoke of the influential position it had attained in the course of its twenty-seven years of existence. The Chairman, in replying, gave a short account of the work and progress of the society during the past year. The toast of "Kindred Societies and Guests" was proposed by Mr. L. A. Bidwell, and was responded to by Sir William Church and Dr. W. P. Herringham. Mr. Aslett Baldwin, who was in charge of the arrangements for the dinner, was heartily congratulated on the successful result of his efforts.

THE annual meeting of the After-Care Association, established thirty years ago, to aid poor persons discharged recovered from asylums for the insane, was held on February 3rd at the house of Dr. Savage, who presided. Amongst those present were the Bishop of Croydon, Mr. H. J. Tennant, M.P. (Parliamentary Secretary to the Board of Trade), Dr. D. Nicolson, C.B. (Lord Chancellor's Visitor), Dr. E. M. Cooke and Mr. A. H. Trevor (Commissioners in Lunacy), Drs. Blandford, Bond, Bower, Robert Jones, Percy Smith, Shuttleworth, and others, including many ladies. The report of the council, read by the Secretary (Mr. W. Thornhill Roxby) stated that much individual care and attention was needed in suitably placing persons, who though recovered from insanity, were frequently the subjects of peculiarities and prejudices. During the year 1908 no less than 388 applications for aid had been received, and with few exceptions the 248 women and 140 men had been successfully helped. Personal influence exercised by the office staff was an essential factor in dealing with these cases, and timely and tactful intervention often prevented relapses. The receipts for the year amounted to £1,054 and the expenditure to £297; £50 had been granted by the City Corporation, and the City Companies had been good friends of the association. A Guild of Help had been instituted in connexion with the association, and two new local branches had been formed. Mr. Roxby pleaded for punctual payment of subscriptions and for new ones, which would be gratefully received at the offices of the association, Church House, Westminster. The adoption of the report was moved by the chairman (Dr. Savage) and was seconded by the Bishop of Croydon, who laid stress on the necessity of supporting this very useful charity, which was the only one existing in the United Kingdom for helping mental cripples who had fallen out by the way to regain the industrial high-road of life's journey. Such a task was often beset with difficulties, but he was thankful to say the word "impossible" had passed out of the vocabulary of the noble profession of medicine. Dr. Nicholson and Dr. Blandford, in supporting, referred to some of the improvements that had taken place in the working of the association, and commended it to a greater share of public support. Mr. H. J. Tennant, Mr. Woolcombe, Dr. Marriott Cooke and Mr. Trevor also spoke, and after the adoption of the report and the election of officers, Dr. Robert Jones, of Claybury, read portions of a paper entitled *The Urgent Need of Helping Mental Convalescents*, pointing out that over 8,000 persons were reported in the Lunacy Commissioners' Blue Book from 1908 to have been discharged recovered from asylums in England and Wales, 1,228 from the London asylums alone, of whom 705 were women, at least one-tenth of whom were friendless and another tenth were without friends able to render them assistance. It was imperative, in the public interest, and from the point of view of preventing relapse, that these poor people should be adequately assisted, and that this society should be furnished with means to extend its beneficent work. The meeting closed with a vote of thanks to the chairman and host.

British Medical Journal.

SATURDAY, FEBRUARY 20TH, 1909.

THE MEDICAL SCHEMES OF THE POOR LAW COMMISSION.

THE Royal Commission on the Poor Laws and Relief of Distress has not avoided that pitfall and reproach of such commissions which is indeed bringing the whole system into discredit—a minority report. In this instance the minority report, signed by four out of the eighteen members of the Commission, is called a separate report, and in length it does not fall far short of the majority report, for it occupies 500 folio pages. We give elsewhere in this issue (p. 479) a general account of both reports, and reproduce textually the principal recommendations with regard to medical relief.

Both reports recommend the abolition of boards of guardians: the majority proposes to set up in their place a statutory committee of the county council or county borough council, to be called the Public Assistance Authority, consisting as to one-half of members of the council, and as to the other of persons experienced in the local system of relief appointed by the council from outside. This authority would set up and supervise Public Assistance Committees, the areas of which would at first be the existing union areas. The recommendation of the minority report is really very similar, since it proposes that the county and county borough councils, strengthened in numbers for their enlarged duties, should replace the boards of guardians and become the Destitution Authorities for the counties, and should appoint education, health, asylums, and pension committees. Both the majority and the minority recognize the necessity for the classification of persons, whether children, aged, sick, able-bodied, vagrant, or feeble-minded, and that to make indoor relief effective it should be given in separate institutions to the various classes.

One of the chief points of divergence between the majority and minority is with regard to medical relief. The majority recommend that medical assistance should be reorganized on a provident basis, in accordance with the recommendations of the report of the British Medical Association on contract practice, and of the results of Dr. McVail's special investigation made for the Commission. It would be the duty of the Public Assistance Authority to co-ordinate, and if necessary supplement, existing medical institutions, and to suggest methods of co-operating with the sanitary authorities and with voluntary hospitals. It would also be its duty to organize an outdoor provident medical service, easily accessible from all parts of the county or county borough, and to include the provision of competent midwives; to develop a nursing service, preferably in connexion with voluntary nursing associations; to subscribe towards these purposes, and to supervise and report on the efficiency and adequacy of the medical institutions and medical service in the county or county borough.

The Public Assistance Authority would appoint a committee consisting of members of the authority, with representatives of the Health Committee of the county, or county borough councils, and of the local Branch or Divisions of the British Medical Association. This Medical Assistance Committee, it is recommended, should have power to co-opt representatives of local hospitals, nursing associations, dispensaries, and registered friendly societies. There would be power to appoint Local Medical Assistance Committees, constituted on similar lines, to which the local administration of medical assistance might be delegated. The Public Assistance Authority, acting in conjunction with the Local Medical Assistance Committee, would organize medical relief both with regard to in-patients and out-patients. It would reorganize existing Poor-law medical institutions with the view of making them as effective as possible for different classes of patients, and it would organize schemes of co-operation between institutions under the direct control of the Public Assistance Authority and voluntary hospitals; it would develop gradually a system of paying and free cottage hospitals in conjunction with voluntary and endowed charities, to include provision for confinement cases, and it would arrange schemes of co-operation between hospitals and the provident dispensaries or outdoor medical service.

The proposals for an Outdoor Medical Service are founded strictly on the provident principle: it is recommended that the Local Medical Assistance Committee should, in conjunction with the local profession, map out its district into convenient medical districts or dispensary areas, utilizing existing buildings in popular places, the doctor's own surgery in medium districts, and a room in a cottage where the population is sparse. The Local Committee would invite free or provident medical institutions, including private medical clubs already existing in the district to fall in with the scheme, and would have power to subscribe to provident dispensaries subject to the sanction of the Local Government Board. Whether co-operation of existing organizations could be secured or not, it would be the duty of a Local Medical Assistance Committee to establish a general system of provident dispensaries, and to offer every inducement to the working classes below a certain wage limit to be members of a provident dispensary, each member to be entitled, (1) to choose his own doctor from the doctors upon the list of the dispensary, (2) to adequate medical outdoor assistance, and (3) to in-patient treatment upon the recommendation of his dispensary doctor. If an applicant for medical assistance is not a member of a provident society he would be entitled to apply and at once be treated by a district medical officer; but the Commissioners hope that ultimately it may be possible to dispense altogether with the service of the district medical officer, and that his duties will be shared among medical men practising in the district. Meanwhile, arrangements might, they think, be made to retain the district medical officer on the staff of the provident dispensary.

The Commissioners recommend that, with a view of enlisting the services of medical practitioners in the locality of a provident dispensary, the British Medical Association should be requested to suggest a general scheme or scale of fees and wage limit to be applied by its local Divisions as local circumstances may suggest. A list of dispensary doctors containing the names of all local medical practitioners

willing to come into the scheme would be formed, and any dispensary member would be entitled to choose his own doctor. The dispensary doctor would have the power to recommend a patient for indoor treatment, whose admission under such conditions would be covered by his subscription to the provident dispensary. In order to meet the case of aged persons and widows with young children, it is recommended that the Public Assistance Committee should have power to pay the necessary fees to make them members of the provident dispensary. There remains the case of those persons who do not belong to provident dispensaries and cannot be induced to join. The Commissioners recommend that in illness demanding immediate treatment the physical condition of the patient should be the first consideration, and that he should be entitled in the first instance to apply to any medical officer belonging to the provident dispensary; but that the relieving officer, to be called in future the Assistance Officer, should be required to report the case to the Public Assistance Committee with the view of recovering the cost and strengthening provident agencies. If the case is not urgent, all necessitous persons should receive medical relief through the Public Assistance Committee. Finally, the Commissioners recommend that medical assistance in the patient's home given at the public cost should be conditional upon the maintenance of a healthy domicile and good habits, and that no disfranchisement should be attached to any form of medical assistance.

The separate report of the minority is a discursive document containing many passages of fervent eloquence, even its summary of conclusions reading more like an article in a monthly magazine than the serious recommendations of a Royal Commission for fresh legislation. It is largely occupied with a discussion of the prevention and cure of unemployment, and suggests the establishment of a Ministry of Labour, one of whose duties it would be to organize a National Labour Exchange. With regard to medical relief, the minority accept the suggestion, considered and rejected by the majority, for a unified medical service in which medical officers of health, hospitals superintendents, school doctors, district medical officers, workhouse and dispensary doctors, and medical superintendents of Poor-law infirmaries—clinicians and sanitarians alike—would all find appropriate spheres. They suggest that the person among all these clinicians and sanitarians—who has “developed most administrative capacity” should be placed in control in each locality, but they do not indicate how this individual is to be selected. They condemn the provident scheme of the majority, for the curious reason that they believe it would lead to an extravagant expenditure of public funds on popular remedies and medical extras without obtaining in return greater regularity of life or more hygienic habits in the patients. They recommend, therefore, the continuance of the outdoor medical service of the Poor Law. They do not give in detail any scheme for carrying out their recommendations, contenting themselves, so far as we can see, with recommending the establishment of a “unified Medical Service on Public Health lines,” believing that it would, by searching out disease, securing early diagnosis, treating incipient cases, enforcing healthy surroundings and personal hygiene, prevent recurrence or spread of disease in contrast to the mere relief of the individual. That

the report of the minority contains many valuable suggestions may be admitted, and as it is to be published in a separate volume as a book, it will no doubt receive all the attention from the public that it deserves; but its proposals with regard to medical relief appear to us to be nebulous and insufficiently considered.

THE HUNTERIAN ORATION.

ON February 15th the Royal College of Surgeons held its annual festival in commemoration of John Hunter, the founder of its unrivalled museum. The Hunterian Oration was delivered by the President, Mr. Henry Morris, to a distinguished assembly, conspicuous in which was the Prince of Wales, who was that day admitted, like his Royal father, to the Honorary Fellowship of the College. It must be as difficult to find anything new to say about John Hunter at this time of day as it is for the Orator whose duty it is year by year to say anything fresh of William Harvey at the sister college. The President was fully equal to the occasion, and among the sixty-four previous Orations there is probably none more interesting in itself, more ingenious in its argument, more felicitous in its illustrations, or more graceful in diction than that delivered on Monday last.

It is likely enough that John Hunter would have been almost as much surprised to hear himself discussed as a philosopher as M. Jourdain was to learn that he had been speaking prose all his life. We should not indeed wonder if he looked upon the “philosophers” of his time in the same light as he regarded the scholars—that is to say, as old women. It suggests curious reflections to note how blind the most distinguished of his contemporaries were to the greatness of the man who was striving to throw light into dark places where secrets of the utmost importance to man were hidden, and laying the foundations of a new knowledge of which they had no notion. Samuel Johnson was intimate with the leading men of his day, and he had a special liking for medical practitioners of all grades. This makes it all the more remarkable that, although William Hunter is mentioned in a letter to Sir Joshua Reynolds, we think we are right in saying that the name of John Hunter does not appear in Boswell's *Life* of “the great Cham of literature,” as Smollett called him. Johnson was to some extent interested in natural history, and he said that Goldsmith was writing a *History of Animated Nature* which he would make as entertaining as a Persian tale, though he thought that if he could tell a horse from a cow that was the extent of his knowledge of zoology. What Macaulay said of Panizzi long afterwards—that he would give ten mammoths for an Aldus—might have been said of Johnson. It may pretty confidently be assumed that John Hunter's lack of literature, to use the language of that day, would in any case have made him seem to Johnson as one outside the world of learning. And Johnson, in an intellectual sense, to the eighteenth century in England exemplified, in Hamlet's words, “the very age and body of the time, his form and pressure.” It must be remembered that Haller and the other anatomists and men of science of that time were all skilled in the learning of the schools. Mr. Morris agrees with Buckle that it was not Hunter's defective education that made him obscure in his statements. He says rightly enough that, “with educated and uneducated alike, the power of clear expression depends on clearness of thought.” But the faculty of clear thought,

though a natural gift, is developed by education. Even when education has done its best, the clearest thinkers will, we imagine, agree with Goethe that "the worst of it is that it is hard to think." John Hunter, in his efforts to express his ideas, reminds one of Burns's description of himself as "a blind 'Cyclops groping round his cave.'" If a poet felt the want of education so keenly, the same want, whether felt or not, must have hindered far more seriously the utterance of a man of science, especially of one who had so much to teach, if he could have put it into words that accurately conveyed his meaning.

Of Hunter's method of inquiry, Mr. Morris says that he combined in an exceptional degree the two philosophic methods—deduction and induction. Though born and brought up in Scotland, where in his day the deductive method of reasoning prevailed, Hunter very largely used the inductive method, which since Bacon has been characteristic of English thought. We think it may be gathered from Mr. Morris's own illustrations of Hunter's method that, while deduction often led him astray, a great part of his permanent additions to knowledge was arrived at by the less flowery and more toilsome but surer road of induction. As Mr. Morris says, "When reasoning deductively he so much relied on his premisses that 'he sometimes refused to accept any evidence by 'which they were impugned.'" This, of course, is the special weakness of the deductive reasoner, and examples of it are still too common even among high scientific authorities at the present day. "It was 'not,' as Mr. Morris says, 'as a logician, but as an 'observer and experimenter that Hunter excelled; 'it was not the beauty of his logic, but the 'industry with which he collected facts, and the 'ability and honesty with which he reasoned from 'them, which made Hunter great.'" His method is summed up in his well-known but too often misquoted recommendation to his pupil, Edward Jenner: "Why 'think—why not try the experiment?" Of course, what Tyndall called the scientific use of the imagination has a great place in research; it is this that makes the difference between those humble but necessary workers whom Huxley called the hodmen of science and the builders of the Temple of Truth. But the unscientific use of the imagination has often led men into quagmires by following Will-o'-the-wisps, whereas facts once established go to make up the solid foothold for which Archimedes asked that he might move the world. Of course, they may be misinterpreted, and in themselves they are like dry bones till life is breathed into them by the generalizing mind that can see their meaning and their relation to each other. Hunter was at once a collector of facts and an interpreter of them. Whether he was ever consciously deductive or inductive in his thought may be doubtful. In any case he had the genius which, like Sentimental Toomy, can "find a wy," and his place is among the immortals of our race.

THE ANTITRYPTIC ACTION OF HUMAN SERUM.

WITHIN a period of little more than ten years a branch of science has developed with such rapidity that even those actively engaged in its study have no little difficulty in mastering all the theories suggested and propounded, and have still more difficulty in selecting from among these theories those worthy of serious attention. The subject is immunity. Although the work of Nuttall stands in very close relation to the

present line of thought and dates back to 1838, the actual revolution in the conception of immunity appears to have taken place in 1897, when Ehrlich enunciated his "side-chain" theory. A few years previously Buchner had written on the bactericidal functions of serum, but Pfeiffer was practically the first to study and explain the phenomenon of bacteriolysis. This he did in 1894. Haemolysis next attracted the attention of workers, and the names of Bordet, Ehrlich, and Morgenroth, among others, are associated with the subject. The discovery of the phenomenon of agglutination arose out of the work which Grünbaum, Gruber, and Durham carried out in 1894, and shortly afterwards independently by Widal. Precipitins and a number of other concepts also date back to about 1897 or a little later.

Since the early work of this kind it appears to have become a fashion to translate all biological phenomena into the action of definite specific chemical substances, and those who accept this view must be prepared to accept an indefinitely large number of constituents in the serum of normal and diseased animals. The mere mention of the large number of cytolsins, the so-called bacteriotropic substances, the allergens, the aggressins, and the anaphylactins, to mention only a few examples, will suffice to show that an almost incredible complexity exists in this branch of research. It might be well to pause and inquire whether the appearance of phenomena, each of which is supposed to depend on one specific substance at least, is sufficient evidence of the existence of such a substance, or whether, like so many physiological processes, the function of a complex structure may not be complicated, according to the conditions governing the exercise of function. In other words, is it not reasonable to believe that blood plasma, which is a highly complex fluid, and which is certainly not biologically identical with serum, may have the property of killing bacteria or inhibiting their growth, of dissolving certain foreign blood cells, of precipitating certain forms of proteid, of exercising now a positive, now a negative chemiotaxis with regard to the leucocytes, and so forth, without possessing a special constituent for each of these phenomena?

One argument against the assumption of special specific chemical substances is to be found in the fact that rabbit's serum possesses a marked haemolytic action for guinea-pig's blood cells. Under what circumstances outside the laboratory can rabbit's serum (not plasma) come into contact with guinea-pig's red blood corpuscles? Yet we are asked to believe that a special substance exists whose one and only function is to dissolve these foreign cells. Perhaps in time much of the confusion which now reigns in regard to these multitudinous phenomena and functions may be cleared up; but so far from this being the case at present, almost each day brings a report of fresh immune "substances."

While the power of human serum to inhibit the action of trypsin is not a new idea, and especially since it has been found possible to immunize guinea-pigs against the action of this ferment, L. Brieger and J. Trebing¹ have grappled seriously with this problem. It had already been shown that the serum of persons suffering from croupous pneumonia exerted a heightened antitryptic power up to the onset of the crisis, when the power is markedly diminished. Ascoli and Bezzola look upon tryptic digestion as due to two components, one of which is contained in the

¹ *Berl. klin. Woch.*, June 1st, pp. 1041-1044, and July 20th, 1908, pp. 1519-1521.

pancreatic juice, while the other, which they call "kinase," is produced by the leucocytes. The increase of the inhibitory action is thus regarded as being due to an antikinase. Brieger and Trebing tested the inhibitory action by mixing serum with a 1 per cent. solution of trypsin in varying proportions, allowing a measured quantity of the mixtures to act on ox-serum plates kept at 55° C. for twenty-one hours. They found that the normal serum inhibited the digestion when 1 part of serum was mixed with 4 parts of the trypsin solution in some cases, while in a few others, when 1 part was mixed with 6 of trypsin, the process was stopped. They record this as a reaction with 1 in 4 or 1 in 6. Next, they examined the serum of a number of persons who were suffering from carcinoma. In nearly all the cases the inhibitory reaction was marked in the proportion of less than 1 in 6, 1 in 10 being the most common. In 4 cases, in 2 of which the diagnosis was not confirmed by the microscope, the reaction was present at 1 in 4. One of the remaining two was suffering from very advanced disease, while the other was a case of epithelioma, which may differ in its essentials from true carcinoma. The serum of persons suffering from diseases other than carcinoma frequently yielded a normal reaction. Nevertheless, the observers found that in cachexia from other causes, such as pernicious anaemia, nephritis, etc., the inhibition was well marked. A curious fact was elicited in testing the blood of persons suffering from cancer and other diseases who had been given pancreatin by mouth; the inhibition decreased, and in carcinomatous cases has returned to normal, to increase again a few days after the drug was left off. In persons suffering from other affections, whose serum showed a normal reaction, the degree of inhibition rose during the exhibition of the pancreatin.

Brieger and Trebing are inclined to the view that, if considered together with the clinical signs, this serum reaction has some value in the differential diagnosis of carcinoma. The claim which Salamon makes of having first pointed out that the serum of carcinoma patients possesses an antiproteolytic action need not confuse the issue, since he did not work with tryptic digestion, and his diagnostic method differed considerably from that of Brieger and Trebing. Whether this antitryptic power of serum can in fact be used for diagnostic purposes depends on the practical experience of clinicians, and can be determined only by careful study; but it would be of considerable interest to learn on what physical, chemical, or biological basis the phenomenon is founded. That it is not purely specific has already been clearly shown.

THE ROYAL COMMISSION ON VIVISECTION.

WITH the evidence of Professor D. J. Hamilton, published in this week's issue, we bring to a close the summary of the evidence given before the Royal Commission on Vivisection. The labour of summarizing so huge a mass of material has not been light. Some idea of the magnitude of the task may be formed from the fact that a rough estimate shows that the evidence has been reduced to about one-quarter of that reported in five Blue Books. Often during the long-drawn-out process we have said with Antonio, speaking to his friends about his sadness, "it wearies me"; and we have no doubt that we should have expressed the thought of many readers if we had added, "You say it wearies you." We had a

strong feeling, however, that the task, though tedious and in some ways disagreeable, was necessary for the enlightenment of many who for one reason or another may not have given attention to the subject. Few people who are not members of Parliament have ready access to Blue Books, and we should imagine that comparatively few of those who enjoy that privilege ever take advantage of it. The whole case for and against vivisection has now been placed before the profession, and we advise all who take part in newspaper or platform controversies on the subject to read and study it carefully. We have purposely given greater space to the antivivisectionists than to the witnesses on the other side; for instance, no fewer than twenty-nine pages of the JOURNAL were devoted to the evidence of Mr. Stephen Coleridge alone. We did our best to bring out all the essential points in their evidence, and the fact that not a single complaint, except one relating to a trifling and obvious misprint, has reached us, may be taken as a proof of the fairness of our abstracts. No one who reads the evidence with a mind open to conviction can, we think, fail to be struck by the flimsiness and futility of the antivivisectionist testimony. One wonders how some of the witnesses could have been put forward to speak of matters as to which they were obviously almost wholly ignorant and to give evidence which was so easily dissipated into air by the lightest touch of cross-examination. It is not surprising, therefore, that antivivisectionists have expressed their opinion as to the manner in which their case has been put forward by some of their representatives in terms the reverse of flattering. It cannot be pleasant to see a cause towards the support of which one has been induced to give money in the belief that it was built on the solid rock of truth crumble into dust because it rests only on a rotten scaffolding of "platform facts."

LONDON TERRITORIAL DEFICIENCIES.

OWING apparently to the popularity of the play "An Englishman's Home" at Wyndham's Theatre, and the efforts of some widely circulated newspapers, there is at the present moment a mild territorial boom in London; but if their general readiness is to be judged from the dilatoriness displayed with regard to the medical branch, it is to be feared that the London County Associations are not fully prepared to take advantage of the interest which has been excited. There will be found at page 504 a short account of the present position of the medical units of the two Divisions. First and Second, of the Territorial Force which London is called upon to provide. It can only be described as extremely unsatisfactory, and there can be no hesitation in asserting that the London County Associations must accept the responsibility for this. The position of the First Division, which has been much assisted by the City of London County Association, is better than that of the Second Division, which is dependent upon the County Association for the rest of London. The main cause of the difficulty in completing the organization is the want of head quarters and drill halls. The First Division, indeed, has head quarters which it inherited from the volunteer companies, but they are not adequate. The position of the Second Division is much worse, inasmuch as it has no head quarters nor any place, except certain drill halls at Woolwich, where men can be trained. Such a state of things is disheartening to the officers, who are giving time and energy without any commensurate result, and must of course greatly discourage recruiting. We are aware that the London County Association suffers from want of money, but

we venture to think that, with a little good will, head quarters and drill halls might speedily be found in some convenient part of western or south-western London.

SPIRITUAL HEALING.

THE Church and Medical Union, to the formation of which reference was made in the JOURNAL of November 28th, 1908, p. 1635, held a meeting on February 16th, at which a paper on The Gift of Healing was read by Lieutenant-Colonel J. S. Hepworth. He said the Church should go hand in hand with the physician and proclaim to the world her mission to heal the sick body as well as the soul. Hitherto no organized attempt had been made to bring into harmony the teaching of the Church and medical science. At Boston, said the lecturer, where healing homes had been established, it had been found that the root of the mischief in the patient had been the deliberate thrusting of religion out of the life. He quoted a paragraph from the report of the Lambeth Conference embodying the principles which the union adopted. In that paragraph it was stated that "medical science is the handmaid of God, and should be fully recognized as the ordinary means appointed by Almighty God for the care and healing of the human body." "The committee," it was added, "believes that discoveries in the region of medicine and surgery come to man through Him who is the light and the Life, the Divine Word." The lecturer went on to say that to be practical Churchmen they should place prayer first. Cases must be taken in hand by their spiritual rulers. "In each diocese there should be a healing house, where resident clergy, selected and set apart for the work by the bishop, should reside in community with resident physicians, selected, say, by the Medical Association, ready at all times to attend to the wants of the people, poor and rich alike. Ultimately every large parish or large centre of religious work should have its resident clerical healer as part of its staff." After some discussion, the Rev. Percy Ellis, Vicar of St. Mary's, Tothill Fields, said the gift of healing still belonged to the Christian community represented by medical men. He deprecated Colonel Hepworth's suggestion that religious healing should be made part of the practical Church organization. Neither the clergy nor the people were prepared for this, and a long time must elapse before they were ready for anything like an organization tacked on to any parish or diocese for that particular work. If a mistake were now made the result would be injurious to a great and good cause. Colonel Hepworth seems to us to have altogether misconceived the purport of the deliverance of the Lambeth Conference which he quotes, and we are glad to note that the Rev. Percy Ellis is alive to the mischief that may be done by too much zeal in the direction of spiritual healing. What has happened at Emmanuel Church, Boston, should be a warning to enthusiasts at home, who, if we may judge from Colonel Hepworth's statements, have not followed the movement so closely as might appear from their confident assertions. We do not think we can give reasonable cause for offence to any sensible religious person in saying that a claim to the possession of the gift of healing on behalf of the Church is a dangerous delusion. The medical profession, we repeat, is willing to co-operate with the clergy, recognizing the great help that a mind at ease is to the efficiency of medical treatment. The saddest words of a dying man we know are those of poor Oliver Goldsmith, who when his physician said to him that his pulse was more disordered than his physical condition seemed to account for, and asked if his mind was at ease, replied, "No, it is not!" But the

doctor and the clergyman have each their definite and distinct sphere, and the intrusion of the one into the other's domain can only lead to harmful consequences.

THE FIGHT AGAINST TUBERCULOSIS IN AMERICA.

THE International Tuberculosis Exhibition, which has been open to the public at the American Museum of Natural History since November 30th, was closed on January 17th. It was visited by 753,301 persons. The exhibition is to be transported to Philadelphia, where it will be under the direction of the Department of Public Health. An attempt is to be made to strike at the root of the enemy by starting a crusade in schools. Dr. James A. McFaul, Roman Catholic Bishop of Trenton, has expressed his gratification that the fight against tuberculosis had at last become concrete, referring particularly to the fact that Archbishop Ryan, of Philadelphia, had recently given instructions that the educational crusade against the white plague should be carried on in all the elementary schools, as well as all the higher institutions of learning, in his diocese. "The result of the movement thus begun," said Bishop McFaul, "will be to enlist the services of 16,000 clergymen in 13,000 parishes in the United States, and the education of 1,250,000 Catholic school children in this respect. The general effect will be that 17,000,000 Catholics in the United States will be enabled to lend their help in preventing the spread of the terrible scourge of "consumption." The Massachusetts educational authorities, acting under a law of the Legislature of 1908, are, according to the *School World*, establishing courses of instruction on tuberculosis in all the schools of the State. In addition to these public movements, many of the private organizations throughout the country have established, and are establishing, open-air schools for consumptive children, it being estimated that about 2 per cent. of the pupils in the larger city schools have tuberculosis. The first public school for consumptive and pre-consumptive children to be established in the United States was opened in Providence, Rhode Island, in January, 1908. The work is done entirely in the open, and the benefits of the fresh-air treatment are combined with the teaching and training of the public schools. Many similar schools have been opened. In addition to these specially-conducted schools, several of the States require that the important facts about tuberculosis shall be taught in the lower grades of the public schools. It is expected that within five years the majority of children in the United States will be taught concerning the evils and dangers of tuberculosis before they leave the lower grades of the public schools. Nor is it only in schools that the campaign is being carried on. The gramophone is being enlisted in the cause. "Don't spit on the floor of your home," is the greeting which Governor Hughes, of New York, received a short time ago as he stepped into the main building of one of the county fairs at which he was to speak. This direction came from the mouth of a large gramophone which was lecturing daily for the Committee of the Prevention of Tuberculosis of the State Charities Aid Association in connexion with one of the exhibits which is being shown at the county fairs throughout the State as part of the effort of this Association to teach the people the cause of tuberculosis and the means of combating it. Other specimens of gramophonic oratory are the following: "To nail your bedroom window shut is to drive a nail in your coffin"; "Work in the fresh air, sleep in the fresh air, live only in the fresh air."

DECLINING SUPPORT FOR ANTI-VACCINATION.

THE National Antivaccination League has fallen on evil days. A circular recently issued by the executive council of the League announces the existence of a great lack of support on the part of the general public. "Owing to various causes over which the council had 'no control,' it is said, 'the income of this League showed a considerable diminution in 1908 as compared with previous years, and had it not been for two 'legacies received during the year there would have been a large deficit.'" Then follows the oft-repeated appeal for funds. Finding it impossible to interest the public sufficiently to induce them to provide the sinews of war for the campaign against vaccination, an attempt is about to be made to tack on a few more "objects." At the annual meeting of the League, to be held on February 24th, a paper is announced on "Should the 'objects of the League be extended?" by Mr. J. P. Swan, who appears to be one of the guiding spirits. As Mr. Swan is actively engaged in a general attack on "Orthodox Medicine," and an attempt to establish the vendors of herbs on an equal plane with registered practitioners, it is not difficult to foresee the nature of the proposals which he is likely to bring forward. It will be interesting to see how the League emerges from the troubles with which it is now beset, and it is not unlikely that the extended objects will act as mill-stones to drag the League deeper into the Slough of Despond into which it has fallen. Since the last annual meeting of the League there have been significant changes among the officers. The services of Mr. Bonner, the paid lecturer and agitator, have been discontinued, and his name has disappeared from the list of officers announced in the *Vaccination Inquirer*. Lukewarm reception and meagre attendance at the meetings organized, together with a depleted exchequer, are possible explanations. The standard of absurd fallacy published in this official organ has risen to a still higher level under the changes in the staff arrangements which have recently been found necessary. In the February issue readers are informed that: "The 'object of the Vaccination Acts is comparable to the 'compulsory dosing of all infants with alcoholic 'drinks with a view of preventing them becoming 'drunkards in after-years. If all our temperance 'friends would only realize this our ranks would soon 'be largely increased." This is very amusing, but, at the same time, it is distinctly an insult to the intelligence of the League's temperance friends.

KNOWLEDGE AND HEALTH.

DR. A. J. COLLIS'S presidential address to the Newcastle Clinical Society was an earnest and eloquent appeal for the further diffusion of knowledge among the people as a means of improving the public health. Dr. Collis touched on practically every source of preventable disease, and showed clearly in each case the direct causal connexion between the public ignorance and the death-rate. Of course there is nothing new in this, so far. "Everybody knows" that a great proportion of the deaths that take place from the infectious and contagious diseases, and the no less important class of diseases due to unsuitable food and insanitary dwellings, are preventable. Everybody knows it, but all this unco-ordinated knowledge is of little avail as yet. As Dr. Collis points out, the consumptive who is allowed to expectorate freely in one district may find himself fined 40s. when he steps across the boundary into another. Three years ago a Royal Commission was appointed to inquire into disease occurring among grouse, but no public money has ever been spent on investigating measles and whooping-cough, two pre-

ventable diseases, each of which kills an average of 14,000 children annually in the United Kingdom alone. Dr. Collis is not content with merely rehearsing the facts, he suggests the formation in each county of a health association to deal with preventable diseases on the lines of the county associations which now control the Territorial Force. A county health association, he suggests, should consist of all the medical officers of health, medical inspectors of school children, certifying factory surgeons, and public vaccinators in the county, and he would make the association responsible to a central body in London with a Minister of Public Health. He would make each association responsible for its own area, and in this way believes that public health administration throughout the country would be co-ordinated while the education of the public in public health matters would be supervised by the association, which would institute lectures adapted to the special needs of the locality, or to the circumstances of any epidemic which happened to be prevalent. Those who attended all the lectures and passed a simple examination would receive certificates, and employers would be encouraged to give preference to young persons who had obtained the certificate. Each association also should have a staff of women health visitors. Further, he suggested that each association should have its own public health laboratory for bacteriological and clinical examinations, and the staff of the laboratory should give addresses at medical societies on recent advances in public health. The scheme is ambitious, but, as Dr. Collis remarks, "The country is already invaded, and we are suffering 'from this cause an annual loss of at least 100,000 'lives and a large number of permanently disabled— 'a loss far greater than the wastages of war have ever 'produced."

TIN IN CANNED FOODS.

AT the close of the South African war large quantities of canned foods were thrown upon the markets and were reimported into this country. On examination of these foods at the various ports of arrival, it was found that several of the consignments had become unsound owing to the development of gas in the interior of the cans, while others were rejected owing to the unsightly character of the contents. Beef essences had become turbid from the presence of dissolved tin. Dr. Schryver states¹ that all canned foods become more or less contaminated with tin as the result of the contact of the food with the tin plate of the can, and that meat extracts and essences take up more tin than most other meat foods—a circumstance to be explained by the acidity of the meat extractives. Canned fruits and lobsters take up considerable quantities of tin, the interesting point being that the tin penetrates the solid foods, so that they contain more of the metal than the surrounding liquid. The quantity of tin taken up increases with the age of the foodstuffs, although with acid foods solution takes place at a greater rate during the first few months. Not only may tin be thus dissolved and absorbed, but lead may also be derived from the solder. Messrs. Ungar and Bodländer found that when minute doses of tin are introduced into animals by subcutaneous injection for a considerable period nutrition becomes affected and paralysis develops. The presence of tin salts in large quantities in food causes irritation of the bowels, and individual susceptibility plays an important part in the intoxication. Although it is difficult to say how much tin is required to cause symptoms, Dr. Schryver thinks that

¹ Local Government Board (Medical Department) Reports of Inspectors of Foods, Dr. G. S. Buchanan and Dr. S. B. Schryver. London: Messrs. Wyman and Sons, Fetter Lane, E.C. (4d.)

much larger quantities of tin would have to be taken than the amounts usually met with in canned foods. Canned foods containing 2 grains of tin to the lb. would probably cause irritation of the bowels, and all such foods, if over two years of age, should be regarded with suspicion. Tins that have become blown should be destroyed. Each can ought to bear the date and the name and address of the maker. The toxicology of tin poisoning is dealt with in a separate chapter, and the calorimetric and gravimetric tests are described. Leach found that after three months very little more tin was dissolved, but in his experiments solid foods to absorb the tin were not present. In Ungar and Bodländer's experiments a tin of asparagus was found to contain 1.88 grains of tin per lb. Weber found in peaches 2.26 and in blackberries 4.20 grains of tin per lb., while in preserved herrings Gunther found 7.2 grains per lb. In some of the canned foods brought from South Africa Schryver found only $\frac{1}{2}$ grain of tin per lb. at the end of six years, but a can of tripe contained 2 grains per lb. and canned lobsters 2.39. Illustrative cases of tin poisoning in members of families who had partaken of such foods show that the chief symptoms were colic, sickness, and diarrhoea, but in every instance the amount of tin present in the food ranged from 1.8 to 13 grains or more per lb. Experience shows that canned foods, such as fruits, when consumed within a few months of canning, although often containing $\frac{1}{2}$ grain of tin per lb., do not in ordinary circumstances occasion gastro-intestinal irritation in the amount usually taken at a single meal, but the ingestion of older foodstuffs containing larger quantities of tin is not without risk. It is not simply a question of the immediate development of symptoms, for, as in the case of chronic plumbism, the possible storing up of the metal in the tissues has to be borne in mind. In the main, experiments show that there is not much probability of serious risk of chronic poisoning by the absorption of non-irritant compounds of tin as a result of a diet which consists largely of canned foods continued over considerable periods of time.

"ANTIVIVISECTION AND THE POOR."

IN THE JOURNAL of February 13th, we quoted a passage from Macaulay's speech in the debate which preceded the passing of the Anatomy Act in 1832, in which, if we may use a Gladstonian phrase, he "smashed, shattered, and pulverized" an objection made by the "Member for Preston" to the effect that the measure was one for the benefit of the rich. We said that we did not know who was the Member for Preston of that day. We have to thank Dr. A. Maude, of Westerham, for supplying the information. It was Henry Hunt, well described by Dr. Maude as "a prototype of many Radical politicians of to-day who are fond of 'expressing very decided opinions on scientific questions of which they have little knowledge.'" Hunt was at one time a farmer in Wiltshire; then he joined the Marlborough troop of yeomanry, and was fined £180 and imprisoned for six weeks for challenging his colonel to a duel. He took to politics, and, after a second imprisonment for assaulting a gamekeeper, he began farming again in Sussex. In this enterprise he was unsuccessful. His true sphere of activity was that of a turbulent politician, and he was again imprisoned after the so-called "Peterloo Massacre" in 1819. In 1830 he was returned to Parliament as Member for Preston. In 1833 he lost his seat, and became a blacking manufacturer. He died in 1838. Romilly calls Hunt "a most unprincipled demagogue," but the author of his life in the *Dictionary of National Biography*, says his own memoirs are the worst evidence against him. To our mind, Hunt's greatest

achievement is that, by his opposition to scientific progress, he succeeded in getting himself immortalized by Macaulay, in whose speech he is enshrined like a fly in amber.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

THE question of the treatment of school children found to be suffering from disease requiring medical treatment is now before the British Medical Association. A number of Divisions have recorded their opinion, but the question is still under consideration. The county councils are trying to settle details as to the payment of inspectors and the provision of proper treatment. We do not propose to touch on the matter here further than to utter a word of warning to educational authorities as to the exercise of a reasonable amount of discretion in regard to the use they make of the reports of their medical officers. This may seem elementary; but that the warning is needed is shown by a document which has just been placed in our hands. It might be expected that the London County Council, which claims such extensive rights over the population subject to its sway, would set an example to less important bodies. The kind of example it sets may, perhaps, be gathered from a letter addressed to a parent not long ago by an education official. It runs: "I have to 'inform you that the Council's Medical Officer ' (Education) has examined your daughter . . . and 'has submitted a report, the following of which ' (sic) is an extract: 'On examination she was 'found to have very foul discharge of both 'ears; on the right side the whole internal 'wall of the tympanum is granulating, and these 'granulations extend into the attic and probably 'into the antrum. A radical mastoid operation is 'urgently needed. The left ear has had a radical 'mastoid operation done, but owing to the fact 'that the bony projections have been badly rounded 'off, it will never heal; it is granulating and 'discharging freely and requires reopening. It is 'proposed to get the child admitted to the — Hos- 'pital in — if the parents' consent can be 'obtained.'" We are not responsible for the English of this extract. We would ask, however, What is likely to be the effect of such a report on an ignorant parent's mind? The reflection which it contains on the handiwork of the surgeon by whom "the left ear has had a radical mastoid operation done," is the point which we think will strike our readers most forcibly. If this kind of report is to be sent about to parents, the results are likely to be unpleasant to all concerned. The children's parents will be alarmed by the technical jargon, which they will naturally interpret as meaning something dreadful; the practitioners who have treated the child in the first instance will feel justly aggrieved by the frank criticism to which their work is subjected by a specialist; while it is conceivable that the latter may be liable to an action for libel. At any rate, such a procedure is scarcely calculated to lead to the promotion of a brotherly feeling between practitioners and specialists, or, as in the present instance, between one specialist and another. Every necessary information for the guidance of the parent could easily have been given without quoting the opinion of one operator on the work of another.

THE INTERNATIONAL OPIUM COMMISSION.

THE International Opium Commission has been continuing its sittings at Shanghai, and has received reports from all the countries represented except Canada, India, and Russia. A memorandum submitted by

China at the meeting on February 8th has been criticized on the ground of hasty preparation. It contained an historical note showing that opium mixed with tobacco was smoked in China in the middle of the seventeenth century, that there had been a decline in the importation of foreign opium from 4,910 tons in 1888 to 3,220 tons in 1906, but that this decline was due to displacement by the native drug, the total production of which in 1906 was estimated at 34,800 tons. The memorandum asserted that the production of native opium had fallen in 1908 to 21,860 tons, but it is added that the figures given are the result of sifting scraps of information received here and there, and are, therefore, only approximate. In the inland provinces the taxation is irregular, and official returns practically unknown. The memorandum estimates that in China, with a population of 400,000,000, of whom 50,000,000 are adult males, the total number of opium smokers is about 13,500,000. The memorandum admits that the clandestine importation of morphine, chiefly from Japan, is increasing, and that such clandestine importation does occur would appear to be proved by the fact that whereas, according to the Customs returns, only 96 oz. of morphine were imported into all China during 1907, there are single shops known to have as much as 1,000 oz. in stock. At a subsequent meeting the memorandum was criticized by Sir Alexander Hosie, one of the British delegates, who said that it showed only a small part of the facts; he pointed out that the revenue collected from the native opium in 1908 in the I-chang Collectorate alone was £695,345, a sum larger than the total revenue from the whole of the foreign opium imported into China during that year. It had been asserted that the area under poppy cultivation had been reduced, but as the acreage was unknown the statement was valueless, nor could he accept the statement that poppy production had been entirely suppressed in the Mukden province of Manchuria, inasmuch as he had seen the crop growing there last summer. Sir Alexander Hosie also asked for information as to the number of smokers registered under the regulations in force in China, but added: "Such information is immaterial to, and should not be allowed to obscure, the main issue—namely, that opium in China is a great evil, and the removal of the temptation the only cure." In conclusion, he said that, in spite of the absence of any well-organized and uniform scheme for accomplishing the task which China has set before her, there could be no doubt that fair progress has been made in several provinces. Much still remained to be done, but the Chinese Government, whose sincerity was beyond question, had the sympathy of the British delegation and of the Commission in its efforts to eradicate the opium evil from the Empire.

THE HUNTERIAN FESTIVAL.

The Hunterian Oration before the Royal College of Surgeons of England on Monday last was attended by the Prince and Princess of Wales. Their Royal Highnesses, who were attended by Lady Mary Forbes-Trefusis, Lieutenant-Colonel Sir Arthur Bigge, and Captain B. Godfrey-Faussett, R.N., arrived at the College at 4 p.m., and were received by the President, Mr. Henry Morris, by the Vice-Presidents, Sir W. Watson Cheyne and Mr. A. Pearce Gould, and by the Secretary, Mr. S. Forrest Cowell. The party were then conducted to the secretary's office, where the members of the Council of the College were assembled, together with Lord Rosebery, who is an Honorary Fellow. The President called upon the Secretary to read the minute of the Council's proceedings

electing His Royal Highness the Prince of Wales an Honorary Fellow. The minute was as follows: "At a meeting of the Council of the Royal College of Surgeons of England, on February 11th, 1909, the President reported that His Royal Highness the Prince of Wales had consented to become an Honorary Fellow of the College. The votes of the Council were thereupon taken in accordance with the requirements of the Charter of 1899, and the President declared His Royal Highness George Frederick Ernest Albert, Prince of Wales, to be duly and unanimously elected an Honorary Fellow of the College." Mr. Morris then handed the diploma of Fellowship to the Prince of Wales, and, after the roll had been duly signed, the Prince was invested with the robe of Fellowship, and the royal party were then conducted by the President and the Vice-Presidents through the college corridor and common room to the theatre, where they received a respectful welcome from the audience assembled to hear the Hunterian Oration delivered by Mr. Morris. The chair was taken by Sir W. Watson Cheyne. On the conclusion of the oration the Prince and Princess of Wales were escorted to the reception room, where tea was served, after which the royal party left the college. Among the specially invited guests present were Adeline Duchess of Bedford, Lady Mary Howard, the Marquis of Bath, Sir James and Lady Reid, Sir R. Douglas Powell, Sir Frederick Treves, and Sir Thomas Smith. In the evening a dinner was held, the President being in the chair. Among the guests were Lord Aldenham, Lord Chylesmore, the Master of the Rolls, the President of the Royal Society of Medicine, the Astronomer Royal, the Treasurer of the Inner Temple, the City Remembrancer, the Master of the Apothecaries' Company, the President of the Royal College of Veterinary Surgeons, the President of Sion College, Sir Clifford Allbutt, K.C.B.; the Director-General of the Royal Navy Medical Service, the Director-General of the Army Medical Services, and Colonel Mark Lockwood, M.P. After the usual loyal toasts, which were gracefully proposed by the President, the memory of John Hunter was drunk in silence. The toast of "The Visitors" was proposed by Sir William Watson Cheyne, and responded to by the Master of the Rolls and Colonel Lockwood. Sir J. Crichton-Browne proposed "The President and Orator," and Mr. Henry Morris, in reply, said that although he had that day delivered the sixty-fifth oration to the memory of Hunter, he did not wish any one whose duty it might be to follow him to imagine that these sixty-five lectures had in any way exhausted the subject. He referred to the work which they were able to do to-day as compared with what was possible before Lord Lister's great discovery, and said that as a profession they hoped to go forward to the achievement of still greater things in the cause of humanity. The College was spending thousands of pounds yearly in procuring volumes which enriched the library, and in adding to and improving that marvellous museum of which the nucleus was formed by John Hunter.

MILK AND NOISE.

THERE would appear at first sight to be little connexion between milk and noise, for what more innocent-looking and suavely quiet and dreamy than the lacteal fluid extracted from placid cows browsing in flowery meads? Yet, if we follow its peregrinations before it reaches the consumer thereof, we shall find that milk leads to an amount of noise that jars the nerves and depresses the vitality of the town-dweller to a quite unnecessary extent. Missing some of the links in the chain of events, we may begin with the nocturnal or very early

morning rattling of the large distributing milk-vans laden with churns, frequently driven at great speed, the roads being clear at that time. Later, but still early in the morning, commences the house-to-house delivery of milk, either by noisy horsed carts with untired wheels or rattling hand-carts. As if this were not bad enough, the people in charge of these vehicles make a point, apparently, of creating as much metallic noise as possible by pitching the milk-cans about and banging the lids, as if to herald rosy Aurora with the sound of timbrels. In addition, the delivery of milk does not seem possible unless accompanied by strange jodellings. Both the sound and the sick suffer from these noises of the milk trade, and complaints to the large distributing companies on this head do not lead to an abatement of the nuisance. The only solution of the difficulty, and one that has been pointed out to some of the managers of the larger concerns, is the abolition of the dirty—not to say filthy—milk can, clean, sealed glass vessels being substituted, the employment of vehicles with rubber tyres, and the stopping of the unnecessary street cries.

MEDICINE IN THE UNIVERSITY OF LONDON.

We hear that a memorandum is in course of circulation to the deans of the medical schools in London and other members of the Medical Faculty of the university, outlining a scheme for the formation of a Faculty Board, which would act as the executive committee of the Faculty. We have already ventured to express the opinion that the affairs of the university cannot be set in order save as the result of an inquiry by a Royal Commission, ending in the grant of a new charter. If, however, in the meanwhile one particular defect in the present constitution of the university, which is paralysing the Medical Faculty, can be put right by a vote of the Faculty itself, as seems to be the case, it can require no argument to convince teachers in the medical schools of the advisability of giving the most careful consideration to the proposal.

THE APPLICATION FOR A CHARTER.

THE *London Gazette* for February 16th contains a formal notice, dated from the Privy Council Office, February 15th, that a petition of James Alexander Macdonald and other members of the British Medical Association, praying for the grant of a Charter of Incorporation, has been presented to His Majesty in Council; and His Majesty having referred the said petition to a Committee of the Lords of the Council, notice is further given that all petitions for or against such grant should be sent to the Privy Council Office on or before the 3rd day of April next.

IN connexion with the announcement elsewhere that His Royal Highness the Prince of Wales was elected an Honorary Fellow of the Royal College of Surgeons of England on the day of the Hunterian Festival, February 15th, it may be of interest to recall that the King had the Honorary Fellowship conferred upon him on June 14th, 1900, when His Majesty was still Prince of Wales. The Earl of Rosebery is an Honorary Fellow of the college, having been elected on the same day as the late Marquess of Salisbury, July 12th, 1900. King Edward the Seventh is also an Honorary Fellow of the Royal College of Physicians of London. It may be added that His Majesty is Patron of the British Medical Association, of which the Prince of Wales is an Honorary Member. As showing the special interest which His Royal Highness takes in medicine, it may be mentioned that he was elected an Honorary Fellow of the Royal Society of Medicine some time ago.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

The King's Speech will probably be disappointing to those who are interested in social legislation, and in particular to those who looked forward, perhaps not with any very sanguine anticipations, to a comprehensive bill dealing with public health administration and the public health service. It would appear that the session is to be mainly devoted to finance, so that, in the words of the Speech, "less time than usual will be available for the consideration of other legislative measures." Among the measures thus relegated to a secondary place, the bills dealing with Irish land and with housing and town planning, which are remainders from last session. A bill for the constitution of trade boards in industries in which sweating prevails is promised, and also a bill to remove certain inequalities of treatment which have been found to arise under the Old Age Pensions Act of last year. Last on the list are bills to amend the law in regard to inebriates, the outcome of the report of the Departmental Committee on the operation of the law relating to inebriates and their detention in reformatories and retreats. A bill dealing with the supply of milk, and another regulating the hours of work in shops, are also promised. The report of the Royal Commission on the Poor Laws receives the unusual honour of being mentioned in the King's Speech, and it is stated that the recommendations of the Commission are engaging the careful attention of the Government. This phraseology appears to indicate that the Government do not intend this Session to introduce legislation to deal with the subjects investigated by the Commission. The Milk Bill, it is understood, will be a measure for unifying legislation by applying to the whole country the provisions of various milk clauses which have been from time to time enacted in private bills.

The Housing and Town Planning Bill, introduced by Mr. Burns on Wednesday, was read a first time. The bill, which is on the lines of that introduced last year, proposes to amend the law relating to the housing of the working classes, and to provide for town planning schemes, provision with respect to the appointment and duties of county medical officers of health, and the establishment of public health and housing committees of county councils. The bill, which is supported by the Attorney-General, the Solicitor-General for Scotland, and Mr. Masterman, will be read a second time on Monday.

Old Age Pensions.—In answer to a question from Mr. Fell, the Chancellor of the Exchequer stated that the number of claims for pensions granted up to January 31st was 613,962, and that the applications still under consideration on January 31st, exclusive of those which were the subject of appeals, were 65,768. The number of claims made up to December 31st last had been 741,306.

* SUPPLEMENT to the BRITISH MEDICAL JOURNAL, January 16th, 1909, p. 25.

AN International Exhibition of Hygiene will be held at Turin during September, October, and November.

A BILL has been introduced into the Pennsylvania Legislature offering a prize of £10,000 for the discovery of a cure for tuberculosis that shall be as effective as the antitoxin of diphtheria.

THE Second International Conference on Leprosy will be held this year at Bergen from August 16th to the 19th. The preliminary programme includes the following subjects: The geographical distribution of leprosy; the forms and diagnosis of the disease; its causes and manner of propagation; its pathological anatomy; and its treatment. The conference will be held under the patronage of the Norwegian Government and King Haakon. The President will be Dr. G. Armauer Hansen, discoverer of the *Bacillus leprae*. The Vice-President is Professor C. Boeck, of the University of Christiania, another recognized authority on leprosy. The Secretary-General is Dr. H. P. Lie of Bergen, to whom all communications relative to the congress should be addressed.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

MANCHESTER AND DISTRICT.

FRIENDLY SOCIETIES AND THE MEDICAL PROFESSION.

THE feeling in Manchester medical circles with regard to the recent conference as to friendly societies is one of disappointment, and the idea is widespread that a much stronger stand should be taken than hitherto. Up to now medical men have only appealed with a sort of deferential humility for better terms from the friendly societies. It is now seen quite plainly that that is useless, and strong measures are demanded. In one large club in Manchester the club doctors smart under the necessity of treating as club patients scores of men far better off than themselves. Men earning even £1,000 a year are not ashamed to take advantage for themselves of this wealthy penny-a-week club, while they can afford to pay guineas to consultants for attendance on their wives and families. So far from being rare, this is quite a common thing in Manchester. Moreover, since the Workmen's Compensation Act came into force, club patients for the merest trifle of an accident call on their club doctor with an eye to some possible compensation. The amount of work done in some clubs has almost doubled from this cause alone, though the fee remains the same as was agreed on some years ago. The friendly societies complained at the conference about the alleged carelessness of club doctors in the giving of certificates of unfitness for work. If they only knew the proportion of certificates asked for, compared with those actually given, they might be surprised by the amount of claims that they would have to meet if the club doctors were less strict. It seems, too, to be quite forgotten that any club doctor who is too strict in withholding certificates may expect very soon to be told that his services are no longer required. For as things are arranged, the club doctor is not engaged by, nor dismissed by, the central organizations, but by a few local members who attend the local club meetings, the very men whose claims for sick pay the doctor has to scrutinize, and it must demand no small amount of firmness for a servant in such a position to tell one of his masters that he is either malingering or even exaggerating his symptoms. In fact, it is felt in Manchester that the whole club system, started originally with the best intentions, needs radical reform in every direction. It is fast coming to this, that the best men will refuse to take clubs—they will give their support rather to such societies as the Hearts of Oak, that simply pay a fee for entrance examinations but do not provide medical attendance. It is freely prophesied that the time will come when the only clubs for medical attendance will be those conducted by medical men themselves in the form of public medical services. The fact is that with the British Medical Association in its present fully-organized state, and the profession with a second string to its bow in the shape of public medical services, it is felt to be high time to cease supplications, and to make demands from the friendly societies, and it is quite certain that the genuine working men will not suffer from such action in the long run.

THE SALFORD UNION INFIRMARY.

The vagaries of the Salford Board of Guardians would be somewhat comical if they were not rather serious. Their latest freak is an attack on the medical staff of Hope Hospital, because, purely in the interests of the patients, the medical men have agreed to prohibit certain concerts which have been held regularly in the hospital. The senior resident medical officer states that the concerts had not been conducted in the best interests of the patients. The patients attending had not got back to their wards till 9.30 p.m. and their return to the wards had disturbed those actually ill in bed. Children have been present who ought to have been asleep long before that hour. Patients suffering from consumption have attended who, both for their own sakes and the sake of those with whom they mingled, would have been better in bed, while the day nurses who had to accompany their patients were deprived of needed rest. The concerts have frequently been held twice a week. This state of affairs has gradually super-

vened on occasional concerts, which, properly conducted, did no harm, and the medical officers thought it was high time to stop it. As is not unusual when anyone disagrees with certain of the Salford Guardians, the most unworthy motives have been attributed to the doctors for their action in the matter. Two guardians said that a merry evening and the "recreative quality of music" would do the patients more good than all the doctors' medicine in Salford. Another guardian said the doctors were not honest in their advice, and, again, that the doctors had not the interests of the patients at heart. It is a good thing for the poor patients that they are not left to the sentimental mercies of certain of the guardians, and if the medical men were not strong in their convictions and fearless in carrying them out, the action of some of the guardians would not tend to getting the best advice from their medical officers.

THE PROGRESS OF TROPICAL MEDICINE.

At a meeting of the Manchester Statistical Society last week, at which Dr. Niven took the chair, Sir Rubert Boyce, Professor of Pathology in the Liverpool University, gave an address on the progress of tropical medicine, in the course of which he said that the remarkable developments in tropical medicine had unquestionably been built upon the foundation of bacteriology firmly laid by Pasteur, and to the same school of thought belonged the further developments in the field of animal parasitology. Just as Pasteur had given us an insight into the means of prevention of infectious diseases, so tropical medicine had shown us how to combat vastly more devastating classes of disease, such as malaria, yellow fever, Malta fever, sleeping sickness, and tropical anaemia. When it had been shown that the *Anopheles* mosquito was the sole carrier of malaria, regulations for its destruction were soon promulgated. First in India and then in Sierra Leone, Ross had organized mosquito brigades to do away with the breeding places of the *Anopheles*, to drain the land, oil the pools, and deal with every patch of water. Rivers, lakes, and large collections of water were for the most part free from the larvae, which were found in small pools by the roadside, ditches, margins of marshes, and so on. As a result of these measures, the mortality among the West Indian regiments serving on the West Coast of Africa had been reduced 75 per cent., while the Grecian League against malaria had informed the Liverpool School of Tropical Medicine that its efforts had had wonderful effects in the plain of Marathon which used to be a hotbed of the disease. In 1906, 90 per cent. of the cases of sickness there were from malaria, while in 1907 the percentage had fallen to 47. At Ismailia, a town of 8,000 inhabitants, there were 1,550 cases of malaria in 1902. Antimalarial operations were then undertaken, and the figures since then have been, for 1903, 214 cases; 1904, 90 cases; and 1905, only 37 cases. Similar results had obtained with yellow fever. In New Orleans an epidemic of yellow fever in 1898 produced 13,817 cases, with 3,984 deaths, while in 1905 the total was 3,384 cases, with 443 deaths. Similar brilliant results had been obtained in Rio de Janeiro, Havana, Panama, and other hotbeds of yellow fever. The facts with regard to Malta fever and ankylostomiasis were cited as showing the value of prophylactic measures, and Sir R. Boyce concluded by expressing the opinion that there was little doubt that in time the tsetse fly would be conquered, and sleeping sickness no longer be a terror throughout wide districts of Africa.

Professor Delépine, in proposing a vote of thanks to Sir R. Boyce, said that the overcrowding of our large towns was perhaps as difficult a problem as that of the jungle, and he wished that the same energy were devoted to combating disease in our midst as had been shown in combating illness in the tropics.

A MEDICAL PLAY.

There can be little doubt as to the success of Dr. Sackville Martin's new three-act comedy, *Cupid and the Styx*, played last week at the Gaiety Theatre, Manchester. It is something of a satire on hospital life in a provincial town, makes extremely light of love and death and suicide and things that ordinary persons take with a certain amount of seriousness. The three medical men represented are little but flirts, all in love with a nurse whose only recommendation is a pretty face, and all imbued with a very high sense of their own dignity. The whole care of Nurse Price is to

make the best catch for a husband; she gets engaged to both the house-surgeons at once, and is ready to take whichever will marry her first. But, fortunately or unfortunately for them, Sir Peregrine Prendergast, the senior physician of the hospital, falls in love with her at sight, and makes her a totally unexpected offer of marriage in writing without any preliminary love-making. She accepts it at once, and the scene between the two house-surgeons when they hear of it is amusing indeed. The comic situations throughout the whole play are decidedly good. The hospital porter, well played by Mr. L. Mudie, is a doddering elderly man who wants a lighter job and thinks that if he can only get the vacant position of public hangman he would be quite satisfied because the work is light—"only drawing a bolt"—and his past experience as hospital porter "used to folks as isn't alive"—has well fitted him for such a post. By far the most powerful part is that of Philip Barton, a bank clerk with a mania for writing plays and poems which are all returned by managers and editors. At last in despair he determines that he will get into the papers somehow even if it involves a reputation as a suicide. This character is well drawn, and Barton's frenzied despair at the idea that his wife and in fact everybody else fails to appreciate his artistic temperament were excellently rendered by Mr. M. Sherbrooke. The portrait is that of a self-centred egoist, who never really intends to commit suicide though he talks like Socrates about it. There is an admirable comic scene in which with a show of frantic earnestness he discusses with the two house-surgeons the easiest and most artistic way to commit suicide and the exact dose of laudanum that will just do the deed; he begs the surgeons to certify when the inquest is held that he was perfectly sane; he takes a small dose of laudanum, is brought into the hospital, the stomach pump is applied, he is walked about and slapped with a wet towel, and recovers. Then the senior house-surgeon, to show him up, gives him a hypodermic injection of water only, and tells him that he will be dead in a few minutes. At once Barton accuses the surgeon of brutal murder and goes into a frenzy at the idea that he has to die after all. The play ends somewhat abruptly, with a bit of sham seriousness on Barton's part when he learns the truth, and this ending is not so powerful as the earlier parts; there is a feeling of something more to come which never arrives. Nevertheless, Barton's part places the play on a high level of comedy. The fun is nowhere coarse, and the bits of practical common sense put in a witty form are often clever. Sir Peregrine Prendergast, who has a good deal to say that is rather prosaic, now and then breaks out into something better, as when he says, for instance, "I don't believe in young men marrying and reproducing their species without first proving that their species is worth reproducing." The acting throughout was capital, and Dr. Martin owes much to the way in which the play was cast. There was no question about the good reception, and he had a most enthusiastic call from a good house at the end. There may be some rather grim jesting about death, and possibly there may be some slight resentment felt at the way in which hospital staffs and nurses are represented. Nevertheless, as a comic satire it is excellent, and perhaps that is all that was intended.

WEST YORKSHIRE.

MEDICAL INSPECTION OF SCHOOL CHILDREN IN BRADFORD.

AN attempt was made some time ago to obtain the insertion of a clause in an omnibus bill promoted by the Bradford City Council giving the school medical officer power to act as a certifying surgeon under the Factory Acts in his district. Through the opposition of Dr. Walker, a member of the Bradford City Council, this clause was deleted, but it came up again at a meeting of the council on February 9th. The resolution was to "ask the Home Secretary to take the necessary steps to appoint the school medical officer in each district as the certifying surgeon under the Factory Acts." Dr. Walker again opposed the proposition and carried the majority of the council with him. Dr. Walker stated that when the subject of school clinics was before the council, he had received a promise that only necessitous cases should be medically treated, but unfortunately it had not been kept. Little or no discrimination was exercised in picking out the children for treatment, and in distinguishing between

needy children and others. In a letter to the *Yorkshire Daily Observer* of February 13th, Dr. William Mitchell, Honorary Secretary of the Bradford Medico-Chirurgical Society, strongly supports Dr. Walker in his protest "regarding the methods of those responsible for the medical inspection and medical treatment of school children in Bradford. . . . Many children," he says, "are being treated at the expense of the ratepayers whose parents are perfectly able and willing to obtain and to pay for private treatment at home. Patients are being filched from them by the school medical officers and treated gratuitously, often against their wish." Complaints are heard in every direction. There appears to be an enthusiasm in the school medical officers for carrying on their work which, however laudable in itself, ignores the feelings and interests of their professional brothers. This should not be impossible of adjustment; it is hoped the protests of the medical profession, and it may be added of the ratepayers, will be duly noted by the authorities and that the school medical officers will exercise the greatest tact and discretion in carrying out their important duties.

BRISTOL.

ROYAL INFIRMARY.

The annual meeting of the Governors of the Royal Infirmary was held on February 9th, the President, Sir George White, who was in the chair, said that Mr. Hale, V.P.R.I.B.A., had consented to act as arbitrator in the open competition for plans for the new buildings. As a result the plan submitted by Mr. H. Percy Adams had been accepted, and the proposed building, capable of further extension, would be erected in Mandlin Street and Alfred Hill. The canvass for annual subscribers had, he said, been very successful, 233 having been added in the year. For the first time in the history of the institution the subscription list had reached £5,000. The deficit of £3,000 on the previous year's working had not been paid off, but Mr. Samuel White still held his offer of £1,000 good if the balance was subscribed. The income for 1908 including legacies was £16,429. Expenditure, ordinary and extraordinary, was £16,849. The President went into considerable detail with regard to the ordinary expenditure, which showed a slight increase on the previous year. The number of in-patients had been 3,869, and out-patients 49,998, a total of 55,867, against 50,092 in 1907. The cost per in-patient had been £3 3s. 10d., against £2 18s. 5d., due to the fact that the patients had been retained longer, an average of twenty-three days, against nineteen and a half in 1907. The various changes in the staff were touched on, and it was reported that the receipts from private sources had reached £2,377, an increase of about £400. The usual votes concluded the meeting.

HANDEL COSHAM MEMORIAL HOSPITAL.

It is very much to be regretted that the committee has been obliged to close part of the hospital on account of financial troubles. It will be remembered that the institution was opened on June 1st, 1907, and it was believed that there was sufficient income from the balance invested after the building and equipment had been paid for to take in 52 patients. By the will of the late Mr. Handel Cosham, a sum of about £140,000 was left to found a hospital for Kingswood and district, and of this over £40,000 was spent in building, etc. The Court of Chancery, in whose hands the money was placed, appointed certain trustees to carry out the details, and a splendid hospital, fully equipped, was built. But apparently the income derived from the invested funds has not been sufficient, and, after a year and a half working, the hospital is so far involved in debt that the closing of two wards has been necessary. How soon they will be reopened again is doubtful, as the closing of half the hospital will not result in much saving.

WALES.

CARDIFF INFIRMARY.

At a meeting of the Board of Management on February 10th, it was resolved on the report of the medical board presented by the Chairman, Dr. Tatham Thompson, to grant Mr. William Sheen permission to give two demonstrations to members of the Royal Army Medical Corps at

the Infirmary. On the recommendation of Dr. Tatham Thompson and Mr. Lynn Thomas, C.B., it was decided to send a limited number of convalescent patients to the Newport nursing home at Bassaleg, when the sanitary arrangements have been extended; the home is beautifully situated, and the drafting of patients into it will make room for some of the many patients awaiting admission to the infirmary. It was reported that during the year 2,245 in-patients and 16,323 out-patients had been treated. The income of the infirmary was £12,102, the expenditure £15,849, and there was an overdraft at the bank of £17,781. As the maintenance of the new wing would involve an annual expenditure of £4,000 an additional annual income of £7,000 was required, and the new wing will not be opened until this has been obtained. From various friends of the infirmary the capital sum of £32,212, yielding an annual income of £1,300, had already been obtained; and the Lady Aberdare League for the collection of shilling subscriptions had met with a great measure of success. Sir W. J. Crossman's scheme for consolidating workpeople's contributions had also borne excellent fruit. The gift of an operating theatre and the casualty wards by the late Mr. Thomas Webb will be commemorated by giving his name to one of the new wards established through the generosity of his nephew.

USK DISTRICT COUNCIL.

At a meeting of the Usk Urban District Council held on February 9th, Dr. H. G. Jenkins, in his annual report, stated that the general health of the district had been good, there having been no epidemic of any kind. The birth-rate was 14.48 and the death-rate 12.5 per 1,000 of the estimated population. The birth-rate was the lowest on record, and the death-rate was slightly below the average. There was only one death registered under 1 year of age, probably a record for the county.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

IRISH IN THE NATIONAL UNIVERSITY.

The members of the "Students' Union"—and a great many more who were not students—held a meeting in the Mansion House, Dublin, last week, and then paraded the streets with lighted torches, in the hope of convincing the senate of the National University that Irish must be made compulsory in that institution. Banners, mottoes, and all the paraphernalia of such a display were shown, and speeches were made by irresponsible people, who could not be accepted as having any opinion on educational matters worth recording.

At the annual National Convention on February 10th, under the presidency of Mr. John Redmond, M.P., the leaguers seized the opportunity to have a declaration made by the members.

Mr. Boland, M.P., availing himself of the statement by the bishops that the question was one for fair discussion, urged the adoption of a resolution declaring that Irish should be compulsory. The last tragedy of a nation was not the loss of its independence, but the loss of its language. They must have Irish from the very first days that the university opened its doors, or it would be nothing but a poor imitation of English and other foreign types.

The seconder (Rev. M. MacBrennan) said there could be no compromise.

Mr. John Dillon, M.P., declared that he opposed the resolution, and was loudly groaned. Why, he asked, was there no agitation against a royal university, and no proposal to pull or burn it down? It was royal, said someone, and, therefore, they tolerated it. He declared that throughout this controversy an entirely false issue had been put before the Irish people by many of those who advocated the cause of compulsory Irish. It had been said and repeated that this was a fight between the friends and foes of the Gaelic revival; that those who were opposed to compulsory Irish were fighting to preserve the university as a reserve for English Catholics and pro-English Irish Catholics. He absolutely repudiated that statement. The real question was one of academic method, and

whether compulsory Irish would best serve or would injure the Gaelic revival.

Dr. Douglas Hyde (President of the Gaelic League) said the only difference between him and Mr. Dillon was that Mr. Dillon thought it would be better to wait before Irish was made an essential, and he (Dr. Hyde) was of opinion it was better to do it now that they had the chance and the power. This university had been established with Irish money, and since they had paid the money they had the right to have some say in calling the tune. Without Irish there was a risk of making it a replica of Trinity College. Irish was the poor man's tongue; and, inasmuch as it was the poor man's tongue, it was banned from the rich man's school.

At first the voting was apparently rather even, but when the motion was put a second time it was declared to be carried.

POPULAR LECTURES ON PUBLIC HEALTH.

At the meeting of the Fermanagh branch of the Irish Medical Association held in Enniskillen on February 6th the following resolution was unanimously passed on the motion of Dr. Leonard Kidd:

Though large sums of public money are paid to those who instruct the public in agriculture, dairying, fruit culture, the technicalities of various trades, the care of cattle, fowls, bees, etc.; and notwithstanding that the community is taxed for the maintenance of hospitals and sanatoriums for the treatment and cure of disease—much of which is preventable—no public money has hitherto been available for the remuneration of those properly qualified to instruct the people in matters of hygiene and the preservation of their health.

Now that the Legislature has at length recognized public health lectures as a subject of technical education and as one entitled to share in the local grants, it is no longer necessary to regard the services of the profession in lecturing and instructing the people as a matter of philanthropy. And while we consider such philanthropic societies as the Woman's National Health Association are deserving of every sympathy and encouragement, we are of opinion that their existence is the strongest possible proof and condemnation of the neglect and incapacity of the Government, central and local, in matters of sanitation and public health.

We are further of opinion that medical men should not lecture under the auspices of such philanthropic societies, or at all, unless adequate remuneration be provided; and we suggest that these societies should co-operate with the county councils for the selection and remuneration of suitable lecturers.

We desire to point out that if medical men continue to give public health lectures gratuitously philanthropy will be usurping the functions of the Government, and local authorities will never be given the opportunity of exercising their newly acquired powers of paying for lectures and instruction in hygiene and public health.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

THE DICK BEQUEST.

MEDICAL charities in the West of Scotland benefit largely by the munificent bequest of the late Mr. James Dick, manufacturer, Greenhead, Glasgow. By his will he directed his trustees, after payment of certain personal bequests and legacies to local charities amounting to £82,000, to allocate the residue of his estate to such Scottish charitable schemes or institutions as they might select. The residue is estimated to amount to upwards of £600,000. The will was contested in the Law Courts to determine whether the directions were sufficiently explicit to constitute a valid bequest. The Lord Ordinary and the First Division of the Court of Session held that the will was not valid, on the ground of uncertainty, and the House of Lords upheld the decisions of the lower courts. Thereupon the trustees advertised that they were willing to consider applications, and were, we believe, inundated by proposals of all types. After careful consideration of all claims, they announced the first allocation of grants amounting to £311,500. Though the main proportion of the funds has been devoted to West of Scotland schemes and institutions, practically every part of Scotland comes in for a share. The bulk of the present grants has been allotted to medical charities, which receive upwards of £230,000.

Owing to the difficulty of realizing the funds, it is expected that it will be a considerable time before the remainder of the funds is allocated.

WESTERN INFIRMARY, GLASGOW.

An extraordinary general meeting of the court of contributors held last week approved of the Provisional Order made to the Secretary for Scotland to provide for the discontinuance of the Glasgow Hospital for Skin Diseases as a separate institution and for the application of the property thereof, and for other purposes. The managers were further empowered to meet all cost and charges incident to the Provisional Order out of the funds of the Western Infirmary.

STUDENTS' REPRESENTATIVE COUNCIL.

The annual conference of Delegates from the Students' Representative Councils of the Scottish Universities was held in Aberdeen on January 29th and 30th. Among the motions submitted and discussed was one by the St. Andrews' delegate that the Scottish universities be petitioned with a view to making diseases of children a part of the final examination for the degrees of M.B. and Ch.B. It was argued that the subject ought to have a permanent place in the final examination. After dis-

cussion an amendment that the Scottish universities be petitioned to make the classes on diseases of children in the various universities uniform, became the finding of the conference. The delegates also discussed the question of the provision of a separate medical college for women students, holding that the present system of co-education of the sexes in several subjects in the medical curriculum was unsatisfactory and undesirable.

REGISTRATION OF NURSES IN SCOTLAND.

The Scottish medical and nursing professions have been for some time back watching the Registration of Nurses Bill. It was felt that the terms of the bill which passed the third reading in the House of Lords and had been sent down to the Commons, were not suitable to Scotland. The opinion was expressed that in the interests of hospital work and of public and private nursing, steps should be taken to secure for Scotland such treatment as would enable it to obtain the fullest possible benefit from a system of registration. With this object in view a meeting of those interested was held, as reported in these columns on December 19th, at the Royal College of Physicians, Edinburgh. This meeting was attended by, amongst others, the Presidents of the Royal Colleges of Physicians of Edinburgh and Glasgow and the superintendents and matrons of all the principal hospitals in Scotland. At this meeting the terms of the registration bill were carefully and fully discussed. While admitting that registration was desirable, and, indeed, inevitable, it was generally felt that registration on the lines proposed would be hurtful to the interests of Scottish nursing. The meeting considered that the work of training nurses would be much better done if a separate registration authority were constituted in each country. The committee then appointed to draw up a scheme of registration suitable for Scotland has now issued its report, and at a further meeting of the committee in Edinburgh it was approved of without a dissenting voice.

The report states that registration is necessary, but the committee considers it very undesirable that the registration and, as a necessary consequence, the training of Scottish nurses should be controlled by a registration council whose head quarters would be in London. If the recent bill became law the training, education, and status of Scottish nurses would be alien in interests and sympathy to Scottish nursing. Considering the excellence of the training given to nurses in the leading hospitals, the proposal to make the examination by the registration council an essential qualification for registration was unnecessary, and would place an undue burden and expense on candidates, and, further, would tend to create the impression that the main object to be aimed at in training a nurse was to enable her to pass such an examination. A much better plan, in the opinion of the committee, would be to leave the examinations, as far as possible, in the hands of the training schools, the registration council reserving such powers of supervision as would enable the council to ensure an adequate standard of attainment on the part of applicants for registration. It was pointed out that the fee of 5 guineas proposed to be charged for examination and registration was excessive, since the majority of those who would be called on to pay it would probably be in receipt of small salaries.

The committee, having formed these conclusions, does not recommend the nursing profession to adopt this bill now before Parliament as applying to Scotland, but advise that a bill which it has drafted should be brought before Parliament exclusively applicable to Scotland. The committee expressed the opinion that the existence of a separate registration council in Scotland would stimulate and promote the training of Scottish nurses in a manner that a registration council sitting in London could not achieve.

The committee also advocates a system of reciprocity, and suggests the insertion in any bill of a clause providing that nurses registered in England or in Ireland should be held as registered in Scotland, and that nurses registered in Scotland should be held as registered in England or in Ireland.

A meeting of those interested in the subject will be held at 3 p.m. on February 27th in the Merchants' Hall, 30, George Square, Glasgow, under the presidency of Lord Inverclyde.

SELKIRK MEDICAL OFFICERSHIP.

Mention was made in these columns of the deadlock which had occurred in connexion with the resignation of Dr. Muir as medical officer of the burgh of Selkirk. The town council offered the position to various medical men, but they all declined. After the last meeting of the council it was understood that Dr. Muir was willing to resume duty at an increased salary. At a subsequent meeting, which was held in private, it was decided that it was impossible to agree to the conditions which Dr. Muir laid down in the event of his resuming office. It was, therefore, determined to advertise for a medical officer. It will be interesting to watch further developments in the case; and it is to be hoped that the members of the medical profession in the neighbourhood will support one another in the endeavour to put the appointment on a proper and satisfactory basis.

ROYAL MEDICAL SOCIETY BANQUET.

The annual dinner of the Royal Medical Society was held in Edinburgh on the evening of February 9th. The Senior President, Dr. W. Kelman Macdonald, presided over a gathering of about a hundred gentlemen. The guest of the evening was Sir Donald Macalister, Principal of Glasgow University. Sir Donald Macalister, in proposing "The Royal Medical Society," said that reverence was due to it as the senior medical society of the United Kingdom. It was still in its vigorous prime, and it had retained not only the mature vigour of age, but all the portentous gravity of youth. A roll of membership that included among its ordinary members Oliver Goldsmith, Charles Darwin, and Joseph Lister, was glorified for all time. Cambridge and Glasgow shared a portion of the glory those names had shed upon the world, and in the name of both universities he made his acknowledgements. He acknowledged on behalf of a third institution which he represented the hospitality of the society to the members of the General Medical Council, and referred to the position the General Medical Council held with regard to education. The kind of education the State had put under its charge was not education for culture, considered as an end in itself. The Medical Acts had a strictly practical end in view. They bid the Council see to it that a medical man possessed "the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery." A university might properly impart to and demand from its medical graduates a higher and wider education than that. It might rightly insist on more "knowledge," but it might not be satisfied with less "skill." Greater proficiency on one side must not be purchased at the cost of less efficiency on the other. The one concerned the reputation of the medical graduate as a man of learning; the other touched the public safety, and it was in the interest of the public safety that the Legislature created the General Medical Council. Modern advances in medical and surgical treatment, in the arts of healing and prevention, put new powers for good into the doctor's hands. But to learn to use them skillfully needed more study in the wards and more practice at the bedside than before. For that more than the second half of the curriculum was required. When the two half-sections were more than the whole would contain, something must give place. Should it be the first half, or the second half, or the whole? There was the practical problem, and he commended it to the Royal Medical Society as a problem worthy of its statesmanship. The one solution that was barred, from the point of view of the public, was that which would crush up or crush out the second half. The public was made up of patients, actual or potential. That was why the public thought it worth while to make legal and educational provision for the production of doctors. After referring to the growth of the Edinburgh Medical School and the efficiency of its clinical teaching, he concluded his remarks by saying that clinical skill could not be crammed, time and a certain detachment of mind were factors in the product. If these were stinted, practical efficiency suffered; and it was by their practical efficiency that doctors, Scottish or non-Scottish, must in the end stand or fall. The General Medical Council would look after the minimum curriculum; that was its function. It was on the superminimal after the bare essentials were provided for, on the higher instruction provided, and on the stricter standards enforced, that the special reputation of a school or university chiefly depends.

COMBATING CONSUMPTION IN EDINBURGH.

Dr. Philip, in an address to the Council of the Edinburgh Charity Organization Society on Concerted Action in the Prevention of Consumption, said that such action was the key to success. In Edinburgh alone about 400 people annually died from consumption. The proportion of tuberculosis in school children was much greater than was commonly supposed. From observations of several groups of school children taken at random in the City of Edinburgh, he found that no fewer than 30 per cent. had tuberculosis. There were in the city a large number of tuberculous nests. The issue was one of considerable magnitude and complexity. The problem was not how to cure a certain number of individuals and restore them to work. The preventive programme must be comprehensive. It was not merely a question of notification or sanatoriums; it must be an organized and co-ordinate programme, such as notification, a tuberculous dispensary, a hospital for advanced cases, a sanatorium for early cases, and a working colony. He believed that there were 4,000 people in Edinburgh who ought to be under surveillance on this account. Dr. Leslie Mackenzie, medical member of the Local Government Board, stated that the Board, so far as that was possible, had given whole-hearted support to the views put forward by Dr. Philip, and hoped to continue to do so.

Cape Colony.

NEW REGULATIONS AS TO MIDWIVES AND NURSES.

New regulations on the subject of the certification of trained nurses and midwives in Cape Colony have, after a long delay, been gazetted. The chief alterations in regard to midwives are that the registration of certificates from outside the Colony is abolished, and examination will, in all cases, be compulsory. The curriculum of a midwife from outside will, however, if equal to that exacted in the Colony, be accepted. Training in a recognized lying-in institution will be compulsory. This must cover a period of three months, and must include a course of lectures, and the conduct, under the direction of a medical practitioner or registered midwife, of at least fifteen cases. In regard to nurses, training schools must henceforth be recognized by specific resolution of the council, having regard not only to the actual number of patients, but to the class thereof, and to the quality and extent of the instruction. The training schools will be of two classes, the first including those having 400 or more patients per annum, and the second those having fewer than 400, but not fewer than 200. In the first class three years' training will be required, and in the second class four years. If the candidate has been trained partially in an institution of one class and partly in one of the other, a period of eighteen months in the second class shall be regarded as equivalent to one of twelve months in the first. The council will continue to register trained nurses who produce approved outside certificates.

Special Correspondence.

BERLIN.

Visit of the King and Queen to the Kaiserin Friedrich Hans—Medical Inspection and Treatment of School Children.

While in Berlin King Edward and Queen Alexandra visited the fine Institute for Medical Post-Graduate Instruction, dedicated to the memory of the late Empress Frederick, the Kaiserin Friedrich Hans für aerztliches Fortbildungswesen. Their Majesties were specially interested in the various collections and permanent exhibitions, which form so notable a feature of the establishment. Its fine, admirably lighted rooms (the institute dates from 1905) contain a permanent exhibition of objects of medical technical industry. Manufacturers know the advantages of presenting these objects to the institute, and practitioners here find an assemblage of all appliances they may require in every branch of professional work, including, of course, surgery, radio-therapeutics, etc. A special department is devoted to chemo-therapeutics, and the chemical remedies so largely manufactured in Germany; there

are separate rooms for casts, for tropical medicine, for balneology, and ample space is reserved for temporary scientific exhibitions. There is a collection also of medical teaching appliances placed here by the Prussian Government, to whom it belongs, and used for lecture experiments and demonstrations. These lectures, which are free to graduates, are given in a lecture-room for 250 hearers. A library and a reading-room for general use are provided, and other rooms, with about twenty working places each, are devoted to practical courses of study in microscopy, bacteriology, and experimental medicine. There is a studio for scientific photography and a workshop for casts. Close to the latter Professor Lassar's celebrated collection of models has found its place. Professor R. Kutner is at the head of this fine institute. To him fell the honour of conducting the King and Queen through the building, and of delivering a short address, illustrated by photographs on the screen, before Their Majesties.

A public meeting, convened by and presided over by Herr Hentig, late Prime Minister of Coburg-Gotha, was held in the Session Hall of the Prussian Upper House on February 10th by the German Central Committee for the Care of the Young (*Jugendfürsorge*). Its proceedings were devoted exclusively to a discussion of the institution of school doctors, its results after ten years' practical experience, its aims, and its limitations. Dr. A. Lewandowski presented a report of the general inquiry instituted by the committee six months ago, and in an able and exhaustive speech commended its outcome. A list of questions, accompanied by a paper of simple guiding maxims, had been sent to the elementary schools (*Volkschulen*) of all places in Germany of over 5,000 inhabitants—524 schools in all. Replies had been received from 468, almost 90 per cent., and formed the basis of the report. It was a gratifying sign, said Lewandowski, that the school authorities in general seemed fully alive to the importance of proper hygienic arrangements in school buildings and playgrounds, and of such measures as special classes for backward and dull children, individual treatment of shortsighted, deaf, neurasthenic, weak-chested, or slightly crippled children, meals for the underfed, dental supervision and treatment, and other aids to health advocated by German school doctors. It was satisfactory, too, that in general the relations between school authorities and school doctors had been of the smoothest. Much good had been effected by parents' evenings, meetings at which school doctors discussed some point of importance, and questions were asked. The dangers of alcohol had been from the first explained and kept before the minds of both children and parents. Useful advice on the selection of a trade suited to bodily condition and physique had been given, and the spread of epidemics in schools had been prevented. It was, however, useless to deny that school doctors did not, and could not, effect all the good of which their office was capable while the limitations that tied it down remained in force. At present the German school doctor's functions were almost exclusively advisory. He examined the pupils at entrance and at stated intervals, and recommended medical treatment where he considered it advisable. But, for reasons of medical etiquette, he was debarred from carrying out that treatment himself, even though he might know that the child, owing to the negligence of the parents or from other causes, was without any medical care whatever. Nor had he any means of forcing the parents to do their duty. When he had diagnosed, say adenoids or the initial stage of phthisis, when he had stated the case and advised special treatment, the school doctor's function was at an end. This, said Dr. Lewandowski, was an ambiguous state of things; in concert with many of his colleagues he raised his voice against its continuance. No one now doubted that the institution of school doctors was a step in the right direction. In the ten years the system had existed it had effected much good and produced a great store of experience. But if it was to have its full share in raising the physique of the nation and stamping out the diseases that were its scourges it must not remain an isolated measure of stunted scope, but must be extended and centralized, must be worked and moulded by municipal and State authorities into a link of that great chain the forging of which Germany, he hoped, would complete before long—a chain of free

medical care for the people, from earliest infancy to manhood and womanhood. The discussion was opened by Geheimrath Freund, of the Prussian Ministry of the Interior. He declared himself in full sympathy with the hopes of the Central Committee, as formulated by Lewandowski. State legislation alone could give the school doctors adequate executive powers. But the financial side—and the question of funds came uppermost in all great schemes—was a matter that concerned the communities more than the State. German communities were freer financially than English, inasmuch as they were entitled to vote funds—without appealing to Parliament—to any purpose they might judge useful to the community at large. Dr. Gottstein, honorary town councillor of Charlottenburg, in a closely argumentative speech, pleaded for enlargement of powers and centralization. The "school doctor" must be henceforth the "school-children's doctor," though this alone would not suffice; for it was an established fact that much of the children's ill-health had its root in unsatisfactory home conditions; and as it was useless to hope for cures while these remained what they were, centralized action was necessary. To be of use the medical care of the people must not be cut up into bits, the one having no official cognizance of the other, but must form a single organic whole.

Correspondence.

BOYS' RACES.

SIR,—Probably those medical practitioners who have the advantage of an extensive practical experience of school boys who regularly run in "school and cross-country races exceeding one mile in distance"—I mean the medical officers to our great public schools—will realize the very unfortunate effect that is almost certain to be the outcome of the laconic letter—we may call it the "certificate"—to Mr. Farmer signed by Sir Lander Brunton, Sir Thomas Barlow, Dr. Goodhart, Dr. Hale White, and Sir Alfred Fripp. One naturally wonders on what grounds these high medical authorities base their assertion that for boys under the age of 19 the continued strain "is apt to cause permanent injury to the heart and other organs." This is indeed a very sweeping generalization; and though it is probable that individual instances of boys who have taken part in long runs have been brought before these gentlemen as patients, I cannot think that they have had opportunities of watching the effects of such runs on the average healthy boy which alone would justify the statement to which these gentlemen subscribe. As with vaccination so with runs, to many nervous parents it is *Post hoc, propter hoc*.

For eight years I was in medical charge of an English public school of about 650 boys, and from the outset was particularly anxious to note any ill-effects from long cross-country runs, for I started on my work as deeply prejudiced against races exceeding one mile in length as any of those distinguished subscribers of the letter. But experience showed that the harm done was a myth, provided, of course, that only the physically sound were allowed to take part in the healthy exercise of "runs."

My experience, at any rate, was diametrically opposed to the statements of Sir Lander Brunton and his colleagues, and I never once came across a boy who, after I had certified him as fit to run, was any the worse even for the long cup race of about nine miles.

It would be very useful if the question under consideration could be made the subject of discussion at the annual meeting of the Association at Belfast.—I am, etc.,

Clifton, Feb. 14th.

P. WATSON WILLIAMS, M.D. Lond.

SIR,—A few weeks ago I was consulted by a senior boy of one of the leading English public schools, who was sent to me by his parents on account of an unusual listlessness which he had shown during the holidays. They further asked my opinion on the advisability of his continuing to take part in the long distance cross-country competition races (five to six miles) in which he took a prominent place. On examination I found a coldness of extremities, slight but distinct cyanosis of the cheeks, and a slightly dilated heart, the physical signs showing unmistakably

that the heart and circulation had been unwisely subjected to some physical strain, and on inquiry I found that the family history showed a very marked tendency to early cardiac degeneration. Needless to say, I vetoed any continuation of the long-distance competition races.

My patient informed me that occasionally after the races he was very much done up, his description of his feelings clearly indicating that his condition on these occasions was not one of healthy exhaustion but more akin to collapse, and yet this apparently escaped the observation of the school authorities. Lest any reader should think that the boy in question was one who welcomed a medical certificate to free him from taking part in a sport which did not interest him, I may add that he not only took a prominent place in the running team to represent his school in competition contests, but he equally excels in every other branch of school athletics. I sincerely trust that Mr. Farmer will be successful in his efforts to attain an urgently-needed reform.—I am, etc.,

Edinburgh, Feb. 14th.

CHALMERS WATSON, M.D.

SIR,—I have read with much interest your remarks upon Mr. Herbert Farmer's letter in the *BRITISH MEDICAL JOURNAL* of February 13th, and having for years participated in both long-distance running and swimming, I feel I can, from a practical point of view, entirely agree with your conclusions that cross-country running does no harm to the average boy, but should not be insisted upon for all boys. One may hold, as a general rule, that if a boy enjoys long-distance running, then it will do him nothing but good; but if it is inkome to him, then he is in all probability physically unfit for it. To my mind, the "sprint," especially the "quarter," is a much more unnatural and severer strain on the circulatory system than the slower long-distance race. If parents would only take the trouble to have their children medically examined occasionally, then any who were unfit for ordinary school sports could have their exercise regulated. I have often seen cases of boys at public schools who were quite unfit to participate in the usual school sports on account of their cardiac condition, but such cases are the exception and not the rule.—I am, etc.,

LESLIE THORNE THORNE, M.D., etc.

London, W., Feb. 13th.

SIR,—I hope you will permit me, as a former winner of the United Hospitals' cross-country race, and one who as a schoolboy was keen on paperchases, to offer a few comments upon this most important question.

No boy who suffers from cardiac disease, or any serious physical disability, should go in for any violent sport such as football, running, jumping, or rowing, but in my opinion the ordinary school paperchases involve a much less serious strain on the heart than any of the faster races from 100 yards to a mile, or a hurdle race, or a short distance steeplechase, and certainly than a boat race.

In an ordinary paperchase, even where there is a competitive element in it, there are so many obstacles, heavy ground to be crossed, and time occupied in looking for the scent, that there is not the same strain upon the heart as in the more violent races to which I have alluded.

Provided, then, that there is proper medical supervision, as there should be for all kinds of boys' sports, and that suitable training is carried out, and the runs adapted to the age of the boys, I am of opinion that there are few more healthy forms of sport for growing boys.

It is possible that the manifesto in question may have been written as a protest against Marathon races, and road races of a similar kind, which are quite another thing, but I think it is due to the profession, and especially to those members of the profession who are medical officers of schools, that some evidence should be brought forward to justify what seems to me a grave attack upon one of our well-recognized forms of school athletics.—I am, etc.,

Leighton, E., Feb. 15th.

CHARLES F. HARFORD.

THE DRAFT CHARTER AND THE REFERENDUM.

SIR,—We wish to draw the attention of the members of the Association to the serious effect which the proposed action, headed by the South-Western Branch, in petitioning the Privy Council against the Draft Charter will have upon the South African Branches of the Association. In the

spirit of combat which has been aroused since the Sheffield meeting there is a possibility of the interests of the members of the Association being forgotten, and it is to be hoped that more reasonable counsels will prevail.

This Branch of the Association in South Africa, Cape of Good Hope, has been looking forward to the granting of the Charter since 1905, mainly for the reason that it might have power to increase its subscription so as to enable it to carry out its duties, which it is unable to do at present on the 4s. per member allowed out of the present subscription of 25s., the deficit being made up out of a balance accumulated previous to 1902, and further, to undertake the duties of medical benevolence and medical defence. A further want is the power to form a South African Committee composed of members from each South African Branch which shall have full power of—

- (a) Levying subscriptions on Branches and members to any amount necessary for carrying out its work.
- (b) Shall control and administer medical benevolence.
- (c) Shall take up medical defence.
- (d) Shall be representative of the Branches in matters of medico-politics and of medico-ethics.
- (e) Shall be the central organizing committee for holding congresses and issuing publications.

The regulations for this committee have been considered by each Branch, and in a few months will be finally settled; but, until the Charter is approved, work in this connexion cannot be entered upon.

To the Representative Meeting in July, 1906, the Special Representative Meeting in May, 1907, and the Exeter meeting in July, 1907, representatives were sent from this Branch and the views of the Branch stated. The subject of the Charter has been discussed *ad nauseam*, and it appears to us that the raising of the method of taking the referendum at the last moment is only with a view of delaying the passage of the Charter and the scarcely veiled hope that success in this will finally kill it.

"The Association" as at present constituted has expressed, after more than adequate consideration, its approval of the Charter, and any counter petition, if successful, can only result in the subject being sent back by the Privy Council to the Association to settle the difficulty and to re-petition that Council when the members have settled their differences.

As the objection is not to the Charter but to one of its Ordinances, we think that this point could well have been left to be settled constitutionally after the Charter has been granted.

We now come to the reason for writing this letter. The patience of our members is becoming exhausted, and unless the constitution of the Association is quickly altered so as to give the Colonial Branches more autonomy and more power to enlarge their scope, there is the very grave danger of a serious fission occurring in the South African Branches, which will threaten their very existence, and from the ashes of which a Colonial Association will rise. Many of us who have belonged to the British Medical Association for years are most anxious to prevent this, but unless more prudent counsels are adopted we fear this result will occur.

We notice that this agitation springs from those, no matter how highly placed, who have not the intimate acquaintance with the needs of the Association and its members, both home and colonial, as those who have occupied official positions for years.—We are, etc.,

A. JASPER ANDERSON,

President.

H. A. MOFFATT,

Hon. Secretary,
Cape of Good Hope Branch.

Capetown, Jan. 27th.

MEDICAL REGISTRATION.

SIR,—Anxiety to many practitioners may be averted, and comfort obtained by many, if you will kindly publish the enclosed correspondence.

To H. E. Allen, Esq., Medical Registrar.

Dear Sir,—I am writing to you regarding our mutual interest. I enclose a card addressed to myself, and request your kindness to inform me whether you have received my reply to your letter of the 1st.

Section XIV of the Medical Act is most unjust to medical practitioners, and should be repealed. It is unfair that if, from any cause, registrars do not receive answers to their single applications, they can erase names from the Register, and that no acknowledgement of an answer is required from a registrar,

from whom a printed postcard would suffice, costing little and relieving much anxiety.

February 8th, 1909.

Reply, dated February 9th, 1909:

We have 32,000 replies to deal with; it has taken three people five days to open them, and they will not be sorted for two or three weeks at least. Your entry has been marked off as correct; no need to trouble further. We shall not remove any name for not answering until we have sent a second (registered) inquiry.

N. C. KING,
Assistant Secretary.

—I am, etc.,

Malvern, Feb. 11th.

STANLEY HAYNES, M.D.

PERNICIOUS ANAEMIA AND PYORRHOEA ALVEOLARIS.

SIR,—I regret that Dr. Byrom Bramwell cannot agree with my statement. I have paid great attention to the oral condition of my cases for some years, and, though no rule is without its exceptions, feel sure that in 99 per cent. the cause of teeth dropping out is pyorrhoea alveolaris.

With regard to the question raised by Dr. Bramwell's friend of the "less obvious symptoms and signs" of this disease, I must say, not being a dentist myself, I see many cases in which I do not feel justified either in assuming or denying its presence without investigation by a competent dental surgeon.

As regards the various points raised, I have followed Dr. Bramwell's example, and enclose a letter from Mr. J. G. Turner of Wimpole Street, which deals with the subject from a dental point of view.—I am, etc.,

London, W., Feb. 12th.

C. WYNN WIRGMAN.

SIR,—The important point seems to be whether Dr. Byrom Bramwell has found pernicious anaemia in a subject definitely free from oral sepsis. The answer to this must be a decided negative. In this case, as Mr. Wynn Wirgman says, the dropping out of the teeth may be taken as clear evidence of the presence of pyorrhoea. Pyorrhoea is by far the commonest cause of "dropping out of teeth," and in the absence of all evidence to the contrary must be accepted as the cause in Dr. Bramwell's case.

As to "atrophia alveolaris praecox," I am inclined to regard it (in common with tabetic alveolar atrophy) as a very unsatisfactory thing—always remembering "There are more things in heaven and earth, Horatio, than are dreamt of in your philosophy." A dry form of alveolar caries, infective and analogous clinically to dry caries—say, of the hip joint—is very common and leads slowly to loss of the teeth, apparently without any septic infection and with no formation of pus. In course of time this dry form of pyorrhoea alveolaris generally merges into the purulent, a pocket here and a pocket there gradually showing definite pus discharge.

It is, I believe, this "dry" form of "pyorrhoea" which has given rise to the idea of early senile decay of the alveoli of the jaws, as well as to alveolar atrophy as an accompaniment of tabes, diabetes, etc.

J. G. TURNER.

Wimpole Street, London, W.

APPLICATION OF MENDELIAN RULES TO THE HUMAN INHERITANCE.

SIR,—What I especially endeavoured to show in my last two letters were two points which Professor Karl Pearson ignores in his letter of February 2nd. However, it is clear from paragraph 4 of his letter that he now understands my method of counting. The two points are:

1. If there had been no children born to the last abnormal (which is quite conceivable) my contention is that, without doubt, Mendelians would have considered Nettleship's chart as conforming to Mendel's rules; for of the 274 individuals descended from abnormal, 134 were abnormal and 144 normal.

If this result is not near enough to that required by theory, then I do not know how it is to be regarded.

2. The second point is that of 98 abnormal parents nearly one-third had normal children only.

Will Professor Pearson kindly furnish his explanation of this striking fact? So far, no more likely explanation has occurred to me than the one quoted in italics in the second paragraph of the professor's letter; and he has not by any means shown it to be an erroneous view. Though it may be "new" and offer difficulties, it is not therefore "absurd."

I am, at any rate, not alone in my view that prepotency may change with the mating, for Professors J. Arthur Thomson and Cossar Ewart go further and believe it may

change in the individual. Thomson, in his *Heredity*, pp. 116 and 117, says:

In large families there is sometimes observable an interesting change in the direction of preponderance in the successive children. With a virile middle-aged father and a much younger mother, the older children may be markedly maternal in the expression of their inheritance, the younger children as markedly of the maternal type. . . . Professor Ewart records the case of a very young pigeon of hooded and filled breed which was mated with an old one not decorated with hood or frill. The result was that the first young were smooth headed and smooth breasted, but that those of later broods had the specialized characteristics of the mother.

I still maintain, in spite of Professor Pearson's scathing criticism, that so long as abnormal continued to be produced in Nettleship's night-blind family, the proportions agreed closely with Mendel's rules; and this was not in a small number of individuals, but in a number sufficiently large to warrant one in feeling satisfied that a close approximation to the correct "average" result was somewhat obtained.

If, then, the chart falls strictly into Mendelian lines up to the point which includes all the abnormal, there seems to be no escape from the conclusion that some new factor must have come into operation where Mendel's rule begins to be inapplicable; and when we know the real cause of dominance we may know what this new factor is.—I am, etc.,

Wrexham, Feb. 9th.

H. DRINKWATER.

PULMONARY TUBERCULOSIS IN CHILDREN.

SIR,—Dr. Mary Williams has supported the views she holds regarding chronic pulmonary tuberculosis in children in an able manner, but her conclusions are based upon somewhat insecure foundations.

To refer first to the death statistics given. Death statistics not based on autopsies are of little value, and the statistics quoted in which the cause of death has been ascertained by *post-mortem* examination draw no distinction between acute and chronic tuberculosis of the lungs. It is scarcely necessary to remark that the vast majority of cases of tuberculosis of the lung occurring in children seen in the *post-mortem* room are either acute or subacute in nature. In the second place, allowing (what I am not prepared to admit) that infection of the lungs in children generally takes place from the intestines, it does not appear to me that such a view supports the contention of Dr. Williams. A caseous bronchial gland, whether infected from the air or from the intestinal canal, may remain quiescent for several years, and when disease of the lung arises from the gland during childhood, the disease is almost invariably acute or subacute in nature. With regard to another heading, when drawing deductions from statistics based upon clinical evidence of chronic tuberculous disease of the lungs in children, it is necessary to know what the observers have considered to be evidence of tuberculosis. Dr. Williams, although she holds a strong view on this subject, seems to be uncertain as to the physical signs of chronic tuberculous disease of the lungs. Again, the symptoms considered by Dr. Williams to be indicative of phthisis are certainly of little value. Speaking broadly, the symptoms mentioned may be said to be those of dyspeptic children, of children the subjects of cyclical albuminuria, or of children physiologically delicate—to use a word of ill-defined meaning, but which must be understood by those who have to deal with children. It is necessary, however, to admit that some of these dyspeptic or delicate children may have tuberculous bronchial or mediastinal glands, but the presence of such glands can very rarely be diagnosed.

Possibly a common ailment in children may sometimes mislead Dr. Williams. This ailment is recurrent fever. The frequency with which a short attack of fever sometimes recurs in children is remarkable, but even in a case in which the fever appears only occasionally, if examination of the child were to take place just after an attack, it is probable that any one holding the views of Dr. Williams would diagnose tuberculosis, especially as some bronchitis more commonly than not accompanies the fever. In this connexion it may be of interest to add that a few years ago I looked up, at their homes, all the cases I could find of children who had been under my care for recurrent attacks of fever associated with bronchitis. In

the majority the attacks grew less as puberty was approached, though in one or two instances chronic bronchitis seemed to be developing. In no case was there any indication that tuberculosis was present.

In conclusion, reference may again be made to the evidence of the *post-mortem* room. Here I believe—and this is a standpoint from which I feel I can speak with some authority—that the evidence is strongly against the frequency of chronic tuberculous disease of the lungs in children. On the contrary, the *post-mortem* room not infrequently shows that cases of chronic disease of the lungs in children, which have been thought during life to be tuberculous, prove to be non-tuberculous.—I am, etc.,

February 12th.

THEODORE FISHER.

SIR.—The somewhat sweeping statements made by Dr. Hamilton Williams in her interesting article on Pulmonary Tuberculosis in Children, published in the JOURNAL for February 13th, can hardly be accepted without further consideration. She starts with the assumption that at about 30 per cent. of autopsies tuberculous lesions are found in the lungs. For children certainly this figure is probably sufficiently accurate, for, without ransacking Europe for figures, statistics from the different hospitals for children in London show that about one-third of those dying in them are found on *post-mortem* examination to be tuberculous, and in the vast majority of these the lungs are affected. But Dr. Hamilton Williams further assumes that because pulmonary tuberculosis is so commonly found after death there must be large numbers of children in whom the disease is present during life in a more or less latent form, and that it may remain latent for periods varying from five to twenty years. Now, of this I believe there is no sufficient evidence; on the contrary, all clinical experience shows that the rapidity with which tuberculous disease spreads in the lungs is generally in inverse proportion to the age of the patient, being rapid in early life, comparatively slow in later life. Certainly, in children, when once tuberculous mischief has started in the lungs, it usually spreads very quickly, and in a markedly disseminate fashion, proving fatal before there has been time for any extensive excavation to occur. Severe symptoms develop with corresponding rapidity, and the reason why children suffering from pulmonary tuberculosis are not found in the London elementary schools is not, as Dr. Hamilton Williams suggests, the inefficiency or carelessness of the medical examiners, but is simply due to the fact that as soon as recognizable physical signs are present the children are usually too ill to attend school. It is true that caseation of the bronchial or mesenteric glands may be latent for long periods, and I shall welcome information from Dr. Hamilton Williams or any one else as to how in the great majority of such cases the presence of these diseased glands can be detected by ordinary methods of physical examination.

To come to personal experience: Out of 120 consecutive autopsies on tuberculous children for which I was responsible, it seemed probable that death was directly due to the tuberculous disease in 94, whilst in 26 it resulted from some intercurrent condition. In 13 of the latter cases the bronchial or the mesenteric glands, or both, were alone implicated, and the diagnosis of tuberculous disease in these would, I believe, have been impossible during life. In the 13 remaining cases there was more extensive tuberculous disease, and in all but one the lungs were affected; with the exception, however, of two or perhaps three instances, the pulmonary lesions were of such a character that they would almost certainly have proved fatal in a few weeks.

Clearly, therefore, in these 120 cases there was no evidence to support the idea that more or less latent disease of the lungs is common in children, and is a frequent precursor of pulmonary tuberculosis in adult life; on the contrary, clinical and pathological findings alike point to the conclusion that, whilst tuberculous disease of the lungs is very frequent in early life, in the great majority of instances it rapidly proves fatal. That is to say, the disease must not be looked for in schools, but amongst children who are ill, either at home or in hospital. If unsuspected pulmonary tuberculosis were at all frequent in early life, it would certainly be met with in autopsies on children dying from other diseases, and until such *post-mortem* evidence is forthcoming I must refuse to

accept speculations based on statistics which are liable to many fallacies.

A few years ago we were taught that pulmonary tuberculosis (apart from the military form) was always due to infection through the respiratory channels; now the pendulum is swinging in the opposite direction, and we are told that in the immense majority of cases the disease is contracted not by inhalation, but by the ingestion of bacilli or bacilliferous products by way of the intestinal mucosa. We have the further statement that the largest part of the tuberculosis which man obtains through his food is by means of milk containing tuberculous matter. If both these statements are correct, it follows that in most cases of pulmonary tuberculosis the tubercle bacilli should be of the bovine type, but notoriously I believe this is not the fact. Will the supporters of the view that the disease is due commonly to infection by milk through the intestine explain this discrepancy? Does the bovine bacillus, when it multiplies in the lungs, undergo a transformation into the human type? I ask in no spirit of controversy, but merely to get a satisfactory answer to a very important question.—Yours, etc.,

London, W., Feb. 16th.

J. WALTER CARR.

THE VACANT POLICE APPOINTMENT IN LIVERPOOL.

SIR,—The attention of the Watch Committee has been called to statements upon pages 435 and 438 in your issue of February 13th, to the effect that the Corporation of Liverpool has taken advantage of a vacancy occurring among the medical attendants to the police force as an opportunity of reducing the pay of the appointment from £80 to £60 per annum.

As a matter of fact the retiring medical attendant was appointed at £60, as have all others appointed to similar offices during the last ten years. The salary is a commencing one of £60, rising by increment of £20 to £80 after five years' service.—I am, etc.,

M. H. MAXWELL,
Chairman of the Watch Committee
of Liverpool.

February 16th.

The Services.

THE TERRITORIAL FORCE.

THE LONDON COUNTY ASSOCIATIONS AND THE MEDICAL ESTABLISHMENTS.

THE part which the county associations are called upon to fill in the scheme of the Territorial Force is very important: a county association is responsible for the administration of the units of the force within its county area, except when called up for annual training in camp, when embodied, or when engaged in actual military service. From the formidable list of its duties we select only those which are pertinent to the subject in hand. The county association is required to provide and clothe the necessary men, to find the necessary drill halls, head quarters, storehouses, etc., to provide saddlery for horses, and to arrange for attendance at drills. It receives a grant from army funds, and the income of an association from this source is regulated by the Army Council on the principle of payments by results: the association itself, however, administers and conducts its own expenditure. To meet the general expenses of administration it receives establishment grants, among which are the following: Administrative medical office of the division, £25; mounted brigade field ambulance, £35; field ambulance, £195; general hospital, £40; sanitary company, £35; and for medical details at special rates according to the establishment in the county. The grant made for a medical office is intended to cover the cost of office accommodation, clerical assistance, postage, stationery, etc. To enable a county association to provide the necessary horses for the instruction of mounted men, and such vehicles as are not issued by the War Department for such units as may require them at times other than that of the annual training in camp, it receives special grants. Among these are for a mounted brigade field ambulance £55, and for each field ambulance £60, but the payment of these grants is subject to a certificate of efficiency from the general officer commanding.

Expenditure in connexion with the provision of such land and buildings as the Army Council may consider

necessary for the proper discharge of its functions by the association is met by grants from army funds, and among the buildings to be thus provided are drill halls and head quarters of units.

The regulations contemplate the probability of a deficit, and a county association is authorized to receive money from private sources, either for general or specific purposes.

London has two county associations, one for the City and the other for the rest of London; there is also a county association for Middlesex. In the scheme of organization for the Territorial Force London supplies two divisions and a mounted brigade.

Each division is required under the regulations to provide, in addition to its staff officers—the Administrative Medical Officer, the Staff Officer to A.M.O., and the Sanitary Officer—the following medical units: Three Field Ambulances, two General Hospitals, and one Sanitary Company.

For various reasons the organization of medical units in London has presented peculiar difficulties, and, in spite of the expenditure of much energy and labour, it has only been possible very recently to complete the arrangements for the First Division while those for the Second are still incomplete. The First Division, although not, so far as we can make out, officially assigned to the City of London County Association, seems to have been particularly favoured by that association. In this division the required three field ambulances, two general hospitals, and one sanitary company have been provided, and are now recognized. The number of officers for the three field ambulances is complete, and they have from 52 to 91 per cent. of men. The sanitary company has its five officers, but only 42 per cent. of men; the two general hospitals are complete. It has for head quarters the former head quarters of the Royal Army Medical Corps Volunteers (London) Companies in Calthorpe Street, St. Pancras, W.C., but these are found to be inadequate.

The medical arrangements of the Second Division are in worse case. There are no medical head quarters for the division, and the only foothold that the head quarters staff has is a small room in Craig's Court House, Charing Cross, and it has been threatened with expulsion even from this. Of the three field ambulances for the division, two, Nos. 4 and 5, have head quarters at the Brookhill Road School of Ambulance, Woolwich; the buildings are, however, inadequate for the purpose, have no suitable drill hall, and do not provide sufficient accommodation for the equipment of even one field ambulance. No. 4 Field Ambulance has in addition a small drill hall and accommodation for two ambulance wagons at Erith, and a lecture room and accommodation for two wagons and harness at Dartford. No. 5 Field Ambulance has a lecture room at Greenwich. Both these field ambulances were formed from the R.A.M.C. (Vols.) Woolwich Companies, and are nearly up to full strength. There are, however, vacancies for officers in both. No. 6 Field Ambulance has been raised recently in London, and 71 men and 7 officers having been obtained, application was last week made for recognition by the Army Council. There are still vacancies for three officers: the number of men who have joined since application for recognition was made raises the total to 94. The unit has been raised under very great difficulties, since there was no nucleus to start with and no head quarters: it was for a time permitted to use the head quarters of the 13th Battalion at Kensington, but for the last three months it could only use it as a drill hall once a week, and a room was obtained in Vauxhall Bridge Road, which has been used for recruiting purposes and as a lecture room; this room is at the present moment the only head quarters the Field Ambulance has, for the 13th Battalion has withdrawn permission to use its hall, as it is required for its own purposes. Repeated applications to the London County Association to provide suitable head quarters have always been met with the reply that until the unit is recognized the Association has nothing to do with it. It was pointed out that if the head quarters were allotted the required number of men would be found in a very short time, but this appeal has met with no response. The requisite number of men has now been obtained, but the County Association does not seem to be making any serious effort to find head quarters.

As to the two general hospitals, the staff of medical officers *à la suite* is complete, and the No. 4 General Hospital has its complement of officers and men, so that application for its recognition will shortly be made. No. 3 General Hospital is not yet formed, but it is probable that the whole of the men will be supplied from the staff of one large firm. The Sanitary Company of this division was recognized last July, but down to the present time

has not been provided with head quarters, although repeated and urgent applications have been made. It has 2 officers and 55 men, who have been drilling with the 6th Field Ambulance. The full complement of a sanitary company is 5 officers and 105 men.

It is hardly necessary to insist that there are a great many points in the above simple statement of facts which reveal an unsatisfactory state of affairs.

The allowance of £25 per annum to provide an office for the administrative medical officer and his staff, and all office expenses, is so inadequate as to be absurd: it would not pay the wages of an office boy. It is true that this is the sum allowed by the Army Council, but it ought to be supplemented by the County Association.

At present men are only supplied with one suit, and it is really dangerous to send men into camp for fifteen days without a change; fortunately, last year the season was dry, but in a wet summer the consequences to the health of the men might be serious.

The want of transport is a serious drawback to the medical units: each field ambulance should be provided with a minimum of three ambulance wagons, three carts, and three modern water carts.

The importance of the Sanitary Company does not appear to be sufficiently appreciated by the County Association, and yet prevention of disease is recognized to be the most important part of the duties of a military medical service, and is the governing factor in the organization of the Royal Army Medical Corps. Yet, as we have said, the Second Division cannot obtain head quarters in which to train their men in their special duties, and in neither division can they receive even elementary instruction in water purification, since the necessary apparatus cannot be obtained.

ROYAL ARMY MEDICAL CORPS.

EXAMINATION FOR ADMISSION.

The following is the official list in order of merit (with the marks obtained) of successful candidates for commissions in the Royal Army Medical Corps at the recent examination in London, for which 57 candidates entered:

Name.	Medical School.	Marks.
H. S. Ranken	Glasgow University	503
J. A. Mansfield	Edinburgh University	504
P. S. Tomlinson	University College, Bristol	505
W. H. O. Richardson	Queen's College, Cork	506
C. T. V. Benson	St. Thomas's Hospital and Cambridge University	509
W. P. McArthur	Queen's College, Belfast	517
E. C. Cusker	Trinity College, Dublin	518
A. W. Bevis	St. Mary's Hospital, London	519
F. W. M. Cunningham	Edinburgh University	520
E. M. Parsons-Smith	St. Thomas's Hospital	521
O. V. Sweeney	St. Thomas's Hospital	522
S. S. Dykes	Edinburgh University	523
J. J. D. Roche	Dublin University	524
R. H. Nolan	University College Hospital, London	525
R. C. Priest	St. Thomas's Hospital	526
M. White	Queen's College, Cork	527
R. C. Paris	King's College Hospital	528
P. G. M. Elvery	Royal College of Surgeons, Dublin	529
H. E. Joynt	Guy's and Durham College of Medicine	530
M. J. Williamson	Aberdeen University	531
A. S. M. Winder	Dublin University	532
W. Mathieson	St. Thomas's Hospital and Cambridge University	533
J. R. Yourell	Dublin University	534
J. R. Hill	Edinburgh University	535
O. L. Franklin	Manchester University	536
H. B. Edwards	King's College Hospital	537
A. D. Stirling	University College, Dundee	538
W. B. Rennie	Marischal College, Aberdeen	539
J. Becton	St. Bartholomew's Hospital	540
G. P. Taylor	Edinburgh University	541

EXAMINATION FOR PROMOTION.

The following is the list of successful candidates at the November examination for promotion of Majors of the Royal Army Medical Corps in technical subjects:

Major I. A. O. McCarty.—(d) ii (already passed in technical subjects).
 Major D. J. Collins, M.B.—Technical subjects (already passed in (d) ii).
 Majors H. A. L. Howell and E. C. Hayes.—(d) ii (have yet to pass in technical subjects).
 Lieutenant C. M. Drew, M.B.—(h) ii and iii (already passed in (d) ii and (h) i).
 Lieutenant A. A. Sutcliffe, M.P.—(h) iii (already passed in (d) ii and (h) i and ii).
 Lieutenant A. G. Cummins, M.B., and Lieutenant H. E. Gottle.—(h) ii (already passed in (d) ii and (h) i and iii).
 Lieutenant R. G. Archibald, M.B.—(d) ii and (h) iii (has yet to pass in (h) i and ii).
 Lieutenant J. B. G. Mulligan and Lieutenant P. S. Stewart, M.B.—(d) ii (already passed in (h) i, ii, and iii).
 Lieutenant T. W. O. Sexton.—(d) ii and (h) ii and iii (has yet to pass in (h) i).

ROYAL ARMY MEDICAL CORPS (TERRITORIAL FORCE).

Major J. Clay, M.B., 1st Northumbrian Field Ambulance.—(d) ii (as required of an officer of the Regular Forces before promotion to the rank of Major).

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following appointments have been made:

- Dr. Rivers to represent the University at Fiftieth Anniversary of the Foundation of the Anthropological Society of Paris.
Dr. Langley, a member of the Board of Electors, to the Professorship of Anatomy.
Dr. Fletcher, a member of the Board of Electors, to the Dowdall Professorship of Medicine.
Dr. H. Starling, M.D., a member of the Board of Electors, to the Professorship of Physiology.
Sir Clifford Allbutt, a member of the Board of Electors, to the Professorship of Pathology.
Dr. Gaskell, a member of the Board of Electors, to the Professorship of Surgery.
Dr. Humphry has been co-opted a member of the Degree Committee of the Special Board for Medicine.
F. C. Stirling, M.A., M.D., Trinity College, has been approved for the degree of Doctor in Science.
The following degrees were confirmed on February 11th:
M.D.—T. M. Neatby, Joh.
M.B.—B. P. Campbell, Cla.; W. K. Kerworth, St. Seiv.
M.B., B.C.—O. R. Smaile, Govv. and Cal.; F. B. Treves, Govv. and Cal.
B.C.—T. W. Wood, Pemb.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on January 27th.

Recognition of Teacher.

Dr. Francis O'Brien Ellison was recognized as a teacher of physiology at St. Mary's Hospital.

Curriculum for the B.Sc. (Pass and Honours) Examination in Physiology for Internal Students.

It was resolved that in and after 1910 the regulations for the B.Sc. (Pass and Honours) degree in physiology for internal students (Red Book, September, 1903, pp. 195, 207) be amended so read as follows:

A.—Pass Degree.

The curriculum in physiology shall consist of:

1. A complete course of not less than sixty lectures on physiology.
2. A practical course of histology extending over not less than three months and occupying not less than sixty hours.
3. A practical course of physiological chemistry extending over not less than forty hours, and including:
The preparation, properties, and methods of estimation of the chief carbohydrates.
The properties of fats, fatty acids, and the common oxy-fatty acids; saponification.
The properties of the chief proteins.
The action of ferments.
The chief disintegration products of the proteins; amino-acids and their derivatives.
Urea, creatine and creatinine; the purin group; uric acid.
4. A course of practical physiology (including demonstrations and practical exercises) extending over not less than six months, and occupying not less than 120 hours.

In this course the student is expected to acquaint himself with the methods employed for the demonstration of the fundamental physiological processes as laid down in the syllabus, and to carry out such chemical manipulations or simple experiments as are comprised therein.

A revised syllabus has also been issued.

B.—Honours Degree.

The degree is open to the following classes of candidates:

- (a) *General Class.*—Students who have passed the Second Examination for Medical Degrees (Parts 1 and 2) as Internal Students.

Such students must, subsequently to attending the prescribed courses in physiology for the Second Examination for Medical Degrees, pursue an approved course of study for the B.Sc. honours degree in physiology extending over at least one year, involving not less than sixteen hours' laboratory work per week, as well as attendance at two at least of the courses of advanced university lectures in physiology of the year previous to the examination. Such students will not be required to present any subsidiary subject at the B.Sc. honours examination.

- (b) *Students who have passed the Intermediate Examination in Science.*

Such students must attend the course in physiology prescribed for the B.Sc. pass degree, and must, in addition, after completion of these courses, have pursued a further course of study extending over at least one year, and involving not less than sixteen hours' laboratory work per week, as well as attendance at two at least of the

following courses of advanced university lectures in physiology of the year previous to the examination.

Subsidiary Subjects.—Human anatomy and morphology, organic chemistry, physical chemistry, physics, zoology, botany.

Assistant to the Professor of Protozoology.

Miss Muriel Robertson was appointed one of the assistants to the Professor of Protozoology, vice Dr. J. D. Thomson, resigned.

Date of the M.B., B.S. Examination.

It was resolved that the examination for internal and external students for the M.B., B.S. degrees held twice in each year should commence on the fourth Monday in October and the first Monday in May.

Appointment of Representatives.

Mr. G. H. Cowen, M.B., B.S., has been appointed a member of the Council of Hatherly University College, Southampton. Mrs. Schary, M.D., M.S., has been reappointed a governor of St. Mary's College, Paddington.

Date of the Advanced Lectures in Physiology.

Dr. W. Bulloch is unable to deliver the course of lectures on prophylaxis against infection announced to be given by him at the London Hospital Medical College.

DEGREES.

The following candidates passed the examination indicated:

INTERMEDIATE MEDICINE.—C. Aids, Guy's Hospital; C. H. Beckus, St. Bartholomew's Hospital; S. G. Billington, University of Birmingham; Margaret B. Blocker, London (R.F.H.) School of Medicine for Women; E. Blackwood, University of Leeds and Guy's Hospital; Florence H. Bousfield, London (R.F.H.) School of Medicine for Women; T. D. Bowen, University College, Cardiff, and University College; G. P. Bradley, London Hospital; B. W. Brown, King's College and Westminster Hospital; A. A. C. Russell, University College; G. B. Buckley, Victoria University of Manchester; Winifred F. Buckley, London (R.F.H.) School of Medicine for Women; A. B. Cardew, Middlesex Hospital; A. E. Clark, University of Sheffield; J. H. Cobb, University of Glasgow; H. St. G. Colton, King's College; L. Corwell, Guy's Hospital; E. G. H. Cowen, Charing Cross Hospital; H. Davies, University College; W. H. Dupré, St. Bartholomew's Hospital; W. H. Eggar, Middlesex Hospital; R. F. Emihson, Charing Cross Hospital; D. B. Evans, University College, Cardiff; G. T. Foster-Smith, Guy's Hospital; Frances J. Preston, London (R.F.H.) School of Medicine for Women; V. Glendinning, Guy's Hospital; Alice M. L. Greaves, London (R.F.H.) School of Medicine for Women; F. W. Hamilton, Middlesex Hospital; H. L. Hopkins, Guy's Hospital; W. H. Laird, St. Thomas's Hospital; L. Levene, University College; G. Marshall, Guy's Hospital; M. Mayers, London Hospital; P. J. Monaghan, Guy's Hospital; Hannah G. Morland, London (R.F.H.) School of Medicine for Women; J. G. Mosley, London Hospital; C. T. Neve, St. Bartholomew's Hospital; T. T. O'Callaghan, Guy's Hospital; W. H. Parkinson, Victoria University of Manchester; B. R. Parmer, Guy's Hospital; E. B. Porter, London Hospital; J. L. Pugh, Guy's Hospital; H. E. Robinson, London Hospital; C. F. Schuler, St. Thomas's Hospital; E. P. Scott, London Hospital; R. G. Sparkes, St. Mary's Hospital; Mildred B. Sturgeon, London (R.F.H.) School of Medicine for Women; F. B. Todd, St. Bartholomew's Hospital; R. T. Vivian, St. Bartholomew's Hospital; G. E. S. Ward, Middlesex Hospital; H. P. Warner, Guy's Hospital; E. H. V. Welch, St. Thomas's Hospital; F. S. Williams, University College, Cardiff; H. W. Williams, St. Bartholomew's Hospital; R. M. Wiltch, University College, Bristol.

* Distinguished in pharmacology. † Distinguished in physiology.

UNIVERSITY OF ABERDEEN.

UNIVERSITY COURT.

Annual Financial Statement.

A MEETING of the University Court was held in Marischal College on February 9th, when Professor Matthew Hay presided in the absence of the Principal who has been indisposed for some time.

The Chairman, as convener of the Finance Committee, in moving the adoption of the report reviewed the condition of the university finances.

General Fund.—The general fund showed a balance on the credit side of £1,334, as compared with a balance of £752 for the year 1906-7. The improved condition was due partly to an increase in the number of students and partly to the raising of the class fees in the Arts Faculty. In 1906-7 the matriculated students numbered 890, while in 1907-8 they were 932, and if the teachers in training who attend university classes are included, the numbers were 1,299, the largest number in the history of the university. The total revenue from class fees payable into the fee fund account, from which the surplus, if any, after paying the salaries of professors, passes into the general fund, was £10,642 in 1906-7 and £11,510 in 1907-8—a gain of £863. The increase of students was confined to the women, who now number one-fourth of the total number of students and nearly one-half of the arts students. The faculty showing the largest growth was the Arts Faculty.

Decrease in Medical Students.—Professor Hay then referred to the decrease in the number of medical students, showing that, in common with nearly all other medical schools, Aberdeen University had had fewer entries in medicine than formerly, but there were now signs that the ebbing of the tide had reached its limit. The Scottish universities could scarcely expect in future to attract any considerable proportion of their medical students from across the Tweed, England and Wales being now

well served by several new universities with an equipment not inferior to their own. If, however, a southern student had decided not to attend the university at his own door, and was attracted by the traditional reputation of the Scottish universities, he ventured to believe that Aberdeen would continue to attract her share of such students, and of students from our Colonies. Aberdeen, both academically and residentially, offered undoubted advantages. The university now possessed laboratories of the newest type, the classes were not of unwieldy size, and there were good hospitals, which had multiplied in recent times, afforded adequate medical and dental instruction. Aberdeen was admittedly one of the healthiest towns in the empire, with a climate suited to vigorous work, as well as to healthy living. There was probably no university town in which students could live more cheaply and comfortably.

Salaries of Assistants and Examiners.—Referring to the salaries of assistants and examiners, amounting to totals of £2,504 and £265 respectively, the Chairman said these could bear to be largely augmented, both by an addition to the emoluments of existing assistants and examiners and by an increase in their numbers. These two bodies of officers required, in the unanimous opinion of the Council, to be increased. The Committee on any scheme of increased staffs and Senatus, the first consideration in the matter being the necessity of securing the best possible committee could not, however, at the present moment encourage the Committee for this purpose, as some of the most important of the university ordinances had been recast, or were about to be recast, and the changes involved might seriously affect the revenue from class fees, and might well wipe out the present surplus.

Extension of buildings.—In the building extension account there was a debit balance of £1,087, but it was noted that the payment of outstanding subscriptions promised to the extension fund would at least reduce the residual burden to the university in regard to this account. It would be a matter of much gratification to the Court and a noteworthy finish to the history of the great extension movement had it been possible to say that the scheme had been brought to a close without any debt.

The Carnegie Grants.—The most valuable financial feature of the year was the payment to the university of the employment grants which had been accumulating in the hands of the Carnegie trustees under their first quinquennial scheme of distribution of grants. The sum thus received last year amounted to £25,000, exclusive of the grants for provisional assistance to the library. This sum was devoted to the complete endowment of the Lectureship in Geology and to the partial endowment of the Lectureship in French. Under the second quinquennial scheme similar grants could become available for the departments of Education, Literature, History, and Constitutional History. During the five years just ended, the university had received £45,000 from the Carnegie Trust. Of this sum, £30,000 had been capitalized for endowments for History, Geology, and French, while £15,000 had been expended on the maintenance of the library, the equipment of laboratories and museums, the provision of certain additional assistants, and the better results, the provision of certain additional assistants, and the better results might be made in some quarters. Whatever criticism may be made by the Trust, all admitted that the payment of class fees by the Trust, all admitted that the grants for the better endowment and equipment and staffing of the university had been of the utmost advantage.

Degree of LL.B.—Professor Hay then referred to the institution of new lectureships in the Law Faculty, which made it possible for the university now to grant the degree of LL.B.

Benefactions. Finally, the Court was reminded of the new benefactions which had been received during the year. Dr. Dey, a member of the Court, continued to give his usual annual donation of \$50 to the library. Another recent member, Dr. Crombie, whose retirement from the Court was so sincerely regretted, and whose unsparring generosity had helped them in their financial emergency, had placed the university under new obligations by his open-handed assistance to the athletic association, the erection of their much-needed pavilion. Professor Traut, another member of the Court, had most generously gifted, in memory of his wife, the sum of £1,000, the interest of which was to be applied to the most commendable conditions, for the assistance of accessions and deserving students. The very valuable Colonel Milne Fund had come into operation last year, and was applied to a similar purpose. It ought to be widely known that certain funds, the bursary funds, were now available for the private assistance of worthy students attending the university. The Rev. Mr. Hill, Buckle, made a further contribution of fifty guineas to the fund, to supplement his previous endowment of the Calthrop Prize in History. The Primrose trustees provided sums for prizes in Law and Agriculture, and the trustees of the late Mr. William Knox had agreed over the sum of £2,134 for the endowment of four bursaries in Divinity and Medicine and for scholarships in Arts. For medical bursaries had come into operation during the year, the management of the fund being in the hands of a special body of trustees.

The report was approved, and the secretary was instructed to send a copy to the secretary of the Scottish Education Department, as required under the ordinance.

VICTORIA UNIVERSITY OF MANCHESTER.

IT is announced that Sir T. H. Holland, D.Sc., F.R.S., has been appointed to the Chair of Geology, vacant through the resignation of Professor W. Boyd Dawkins. Sir T. H. Holland will, subject to the sanction of the Secretary of State for India, resign the post of Director of the Geological Survey in India, which he

has held since 1903, and will also resign the Readership in Geology in the University of Calcutta. It is expected that he will enter on his duties in Manchester next October, and meanwhile the department of Geology will remain under the supervision of Professor Boyd Dawkins, who has been appointed Honorary Professor in the University.

It has been arranged that the Bishop of Salford should give two lectures on Wednesday evenings, March 17th and 24th. The subject of the first lecture will be Medicine and the Medical Science in Ancient Iran; the lectures will be open to the public without charge.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

AN ordinary council was held on February 11th, Mr. Henry Morris, President, in the chair.

Election of the Prince of Wales as Honorary Fellow.

The President reported that H.R.H. the Prince of Wales had graciously consented to become an Honorary Fellow of the College. The Council thereupon unanimously elected His Royal Highness an Honorary Fellow.

Diplomas.

Diplomas of Membership were issued to 81 candidates found qualified at the recent examinations. Diplomas were also issued jointly with the College of Physicians to 13 candidates found qualified in Public Health.

Board of Examiners in Dental Surgery.

Mr. C. T. Dent was appointed on the Board, in the vacancy occasioned by the retirement of Mr. G. H. Makins.

CONJOINT BOARD IN ENGLAND.

BOARD IN ENGLAND.
At a meeting of the Council of the Royal College of Physicians, on January 28th and of the Council of the Royal College of Surgeons on February 11th the Diplo. of L.R.C.P. and M.R.C.S. were conferred upon 31 candidates who have completed the Final Examination in medicine, surgery, and midwifery of the Examining Board in England and have complied with the by-laws. The following are the names of the successful candidates, namely:

[illegible]

CONJOINT BOARD IN IRELAND.

THE following candidates ~~have been approved~~ at the examinations indicated:

FINAL PROFESSIONAL.—J. J. Barry, C. H. Bryan, F. S. Crean, J. J. Cuskelly, C. J. B. Dunlop, J. J. Dwyer, J. Ellenbogen, D. J. Harty, P. Maquire, J. O'Brien, M. C. O'Hara, D. O'Sullivan, W. G. Ridgway, H. N. Ritchie.

DIPLOMA IN PUBLIC HEALTH.—Captain W. O'S. Murphy, I.M.S.,
M.B.R.U.I.; S. Poole, M.D. Univ. Edin.

Medico-Legal.

WHAT IS AN ACCIDENT?

THE much-vexed question. What is an accident within the meaning of a policy of insurance? has once more come before the courts for consideration. The companies make every endeavour to avoid accepting liability for any death caused by disease or other intervening cause. A case which was heard in the Court of Appeal last week shows how difficult it is to frame a policy which will effect this object.

It appeared that by the terms of a policy the company undertook that if at any time during the continuance of the said policy the insured should sustain "any bodily injury caused by violent, accidental, external and visible means, then, (a) in case such injury should within three calendar months from the occurrence of the accident causing such injury directly cause the death of the insured, to pay to the legal personal representatives of the insured the capital sum of one thousand pounds." The policy further provided as follows: "Provided always and it is hereby as the essence of this contract agreed as follows:—

"3. That this policy only insured against death . . . where accident within the meaning of the policy is the direct or proximate cause thereof, but not where the direct or proximate cause thereof is disease or other intervening cause, even although the disease or other intervening cause may itself have been aggravated by such accident, or have been due to weakness or exhaustion consequent thereon, or the death accelerated thereby."

The insured when hunting, while endeavouring to jump his horse over a fence in which a strand of wire was concealed, was violently thrown to the ground upon the far side of the fence, which was a few feet lower than the side from which he took off. He fell upon his left shoulder and side. The ground was very wet, and the arbitrators before whom the case came in the first instance found as a fact that he was wet to the skin by the fall. They also found as a fact that as the result of the fall the insured suffered no trauma or wound to the body or lung, but that he did suffer a severe shock to the nervous system whereby the general vitality of his body was impaired. After the fall the insured remounted his horse and rode towards home. He was overtaken as soon as possible by his second horse, on which he then continued his journey home at a trot, where he arrived at about 2 p.m. The arbitrators found as a fact that to ride home in the way he did was, in the circumstances, the course least likely to aggravate the effects of the accident, and was rendered inevitable by it. The effect of the shock from which he suffered was to lower his general vitality, and the effect of the ride home in his then condition was to lower his vitality still further. The cumulative effect of both these causes, but not the effect of either exclusively of the other, was to lower the general vitality of his body to an extent which made attack by the pneumococcus possible, and the arbitrators found that onset thereupon took place one and a half hours after the accident.

The course of this disease the arbitrators found upon the evidence to be as follows: The pneumococcus is generally present in the respiratory tracts of the normally healthy, but remains innocuous by reason of the resisting power of the body and of the lung in particular. If the vitality of the lung is lowered either directly or locally by physical injury to it, or indirectly by the general vitality of the body being lowered, the resisting power of the lung, together with that of the other organs, is impaired, and so continues until the vitality is restored. When the resisting power is impaired the pneumococcus is enabled to settle upon the lung, and, while it remains impaired, to multiply there.

The Court of Appeal held that the direct or proximate cause of the death included all those things which could fairly be considered as attendant results of the accident: that the words "disease or other intervening cause" meant a cause independent of the accident; and that the death was the direct result of the accident.

STATUS OF AN UNREGISTERED DENTIST.

IN a judgement issued by Sheriff Thomson (Hamilton), in connection with a case at the instance of a dentist against a customer for the recovery of a sum for remaking a set of teeth, he dealt with a question as to the power of an unregistered dentist to recover fees for work done. The pursuer's agent cited the judgement of the English court in support of his contention that the Dentists Act of 1878 prohibited an unregistered dentist from recovering charges for operations, such as teeth extraction. The Medical Act of 1886 was quoted by the defendant to show that the prohibition embraced charges for other dental operations. Sheriff Thomson took this view, holding that the pursuer was not entitled to recover payment for the work done; he granted absolvitor, with expenses.

FEEES TO MEDICAL WITNESSES FOR GIVING EVIDENCE AT INQUESTS IN WORKHOUSES IN IRELAND.

DR. DANIEL CROWLEY (Coroner for S. Division, Galway, Loughrea), writes: Omitting certain unnecessary words from paragraph xxxii, 9 and 10 Vic., cap. 37, Coroners Act Ireland, the following will be found:

That when any Inquest shall be holden on a person who has died in any public Hospital, or Infirmary or in any Building, or Place belonging thereto, or in any County or other Lunatic Asylum, or in any public Infirmary, or other public Medical Institution, whether the same be supported by Endowments or by voluntary subscriptions, then the Medical Officer whose Duty it may have been to attend the deceased person is not entitled to the fees or remuneration herein provided.

A workhouse hospital in Ireland is not a public one, neither is it supported by endowments or voluntary subscriptions: it is only for the poor, and consequently I hold the medical officer is entitled to his fee for giving evidence. There are people treated besides the poor, but the medical officer is not entitled to any remuneration from them for his services. I am twenty years a coroner and have two workhouses in my district. I have always paid the medical officer the usual fee when holding inquests in either of them, and have held inquests in two others when acting for adjacent coroners, and have done the same, but now a coroner cannot act outside his own district since Mr. French, M.P., Coroner for Wexford, rushed his bill through the House of Commons last August. Mr. French did not consult any of the C. Galway coroners when pushing his bill, and that would have been the time for doctors of public medical institutions to get paragraph xxxii repealed if they had only known.

CUSTOM AS TO ASSISTANTS.

R. R. R. asks: (1) Should an outdoor assistant be allowed to put up his name plate on the house in which he resides? What is the custom or law on the subject? (2) Is it customary for an outdoor assistant to provide himself with the usual surgical and obstetrical instruments, such as clinical thermometer, midwifery forceps, Higginson's syringe, the usual pocket case of instruments, and hypodermic syringe?

*. (1) There is nothing illegal in an outdoor assistant putting his name plate on the house in which he resides, but it is not customary. Most principals would object to it, as it might seem to the public to imply a partnership, which as a matter of fact did not exist. (2) It is customary for the principal to supply all such instruments, and any others that may be necessary for use in his practice. Even if an assistant may possess any of such instruments, the principal has no right to expect him to make use of them while in his service.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

THE DUTIES OF NURSES.

IGNORANS.—We are informed that hospital nurses are taught to make the patients wash their private parts for themselves, except in the case of helpless patients, in fevers and the like, where the nurses have to do it.

CONTRACT NOT TO PRACTISE.

A. writes that thirty years ago he agreed not to practise in B's district; the wording of the agreement is that "the said A. will not carry on or assist in carrying on the said profession, business, or calling of surgeon or apothecary in" B's district, and goes on to say that A. may practise in a small town near called Z., where A. lives and has his surgery. (1) A patient of A.'s of several years' standing calls at his surgery in Z. with her child for treatment, and receives no medicine for which she pays. When told by A. that the child should be seen in the morning she mentions that she has moved to another village, which is in B's district. A. at once tells the woman to send for B. in the morning. He asks, Does this constitute a breach of agreement, as the child was living in B's district, but attended in Z., where A. has permission to practise? (2) Would it be a breach of agreement for A. to attend at his surgery in Z. a genuine patient who lives in his district, but who is temporarily living in B's district, the patient having never been attended by B.?

*. (1) Yes, this is a breach of the agreement, but as A. committed it unwittingly, and so soon as he knew referred the case to B., it would hardly be a good foundation for an action for breach of contract: but it would have been better if A. had written a note to B. to explain. (2) No, this would not, in our opinion, constitute a breach of agreement. We may say that in such cases there should be a fair and liberal interpretation of the contract on both sides, and so long as there is an obvious intention to keep loyally to it, we do not suppose any difficulty will arise about such small points.

THE ADVERTISING DRUGGIST.

H. K. writes to complain that a firm of druggists has sent a circular to the matron of his hospital drawing her attention to the value of a certain culture of the lactic acid bacillus, and offering, if their preparation is used, to assist by making bacteriological examinations of the finished product.

"Our correspondent is of opinion that such a communication should have been addressed not to the matron but to the medical staff, and we agree that all matters of this kind should be addressed to the secretary of the hospital rather than to the matron. In any case, however, the matter is one for the decision of the medical staff.

MEDICAL ETIQUETTE.

PEN writes: A. being ill, and B., his assistant, doing his work, a patient who did not like to be attended by an assistant called in C. We are asked to say: (1) Would it be considered professional for A., who has recovered, to write to his patient or to C., stating that he is now able to resume his work? (2) What is the etiquette on C.'s part when he knows that the reason for his attendance on A.'s patient is that A. was ill?

"A. may write to his patient and say that he is well again, and will be glad to resume charge if so desired. (2) C. should express his willingness to hand over the case to A., but if the patient desires it he may continue to conduct the case to its termination.

PUBLIC HOSPITALS AND PRIVATE NURSING.

GENERAL PRACTITIONER sends a copy of a circular issued by a provincial hospital enclosing a card of terms for nurses supplied from the hospital, and stating that all the nurses engaged on the hospital's private staff have had a full training of three years. The circular is signed by the senior physician and senior surgeon. Our correspondent raises the question whether this does not involve an amount of undesirable advertising on the part of the signatories.

"Some hospitals endeavour to help their funds by supplying private nurses, and presumably the circular was issued as an advertisement to promote this object. It would have been better, however, if it had been signed by the secretary and the matron instead of by any of the medical and surgical staff.

Public Health

AND

POOR-LAW MEDICAL SERVICES.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.

A MEETING of the Council of this Association was held at 9, Cophall Avenue, London Wall, E.C., on February 4th, Dr. Balding, J.P., in the chair.

Superannuation.—A member about to retire from his Poor-law appointments, one of which he had held for forty-eight years but the other for only twenty, inquired whether he was entitled to the same pension as if he had held them both for the full term of forty years. It was considered by the Council that he was entitled to be paid on the same scale as if he had held both for the full term of forty years; that the only points that could be taken in estimating his pension under the Superannuation Act of 1896 were, (1) How long he had been in the Poor-law service; (2) what was the amount of his Poor-law salaries at the time of his retirement?

Medical Inspection of School Children.—Another member wrote complaining of the extra work that had been brought upon Poor-law medical officers through the working of the provisions of the Act with reference to the medical inspection of schools, and asking if something could not be done to obtain extra remuneration for work of this nature. After some discussion, the Council decided that no steps could be taken until it had better evidence as to the amount of extra work entailed. Another member complained of the recent Notification of Tuberculosis Order issued by the Local Government Board, especially at the postponement of a charge made against him, and given and of the smallness of the fee. The Council considered that it was too early to make representations to the Local Government Board, and that it would be better to watch for a time the working of the Order.

Dismissal of Medical Superintendent.—A case was considered in which the appointment of a medical superintendent of a Poor-law institution had been determined by the board of guardians, presumably in consequence of a charge made against him by the matron. This charge had never been investigated by the guardians, who had simply postponed its consideration for three months, and had then determined the medical superintendent's office. It appeared that in this case the guardians had full power to appoint to and determine the office without requiring the consent of the Local Government Board, so that the officer was entitled at the instance of the guardians. The solicitor to the association thought that the postponement of the matter by the guardians had been to give the accused time to bring an action against the matron, and that, as this had not been done, they

had dismissed him. The letters of the complainant showed that the institution in question was in an unhealthy state, and that its administration seriously required looking into. After some discussion, in the course of which several of the members present expressed their regret that the complainant had not promptly sued the matron for damages, it was decided to bring the facts of the case before the Local Government Board, and satisfaction was expressed that the Local Division of the British Medical Association had intervened in the matter.

Alleged Illegal Appointment.—A letter was read from the Local Government Board in answer to the complaint of the association with regard to the alleged illegal appointment of a district medical officer by the Driffield Board of Guardians. In answer to the complaint that no advertisement had been issued by the guardians, and that after the election, a licentiate had been paid for by them until the officer elected could take up his duties, it was stated by the Local Government Board that the appointment was legal, as notice had been given of the election at one of the two preceding board meetings according to Article 156, General Orders, July, 1847, and that with regard to the payment for licentiate, objection must be raised before the local auditor. The opinion of the Council was that when such notices of election were given under Article 156, the proposed salary of the officer was also stated, or it was presumed that the salary would be the same as that of the predecessor of the officer to be elected. As in Article 157 it was specially laid down that the salary must be stated in the advertisement issued for such an officer, it seemed reasonable to suppose when the alternative notice was given at a preceding board meeting, that there also the salary would be mentioned. The honorary secretary was instructed to write again to the Local Government Board, and make inquiries on this point. It was also decided to instruct if possible one of the Driffield ratepayers to appear before the Local Government Board auditor, when he made his periodic audit of the accounts of the guardians.

HEALTH OF CARDIFF.

The estimated population of the city of Cardiff in the middle of the year 1908 was 191,446; 5,172 births and 2,538 deaths were registered, equivalent to a birth-rate of 27.0 and a death-rate of 13.2. The number of deaths from zymotic diseases was 219, and there were 644 deaths under 1 year of age, yielding a zymotic death-rate and infant mortality-rate of 1.14 and 124 respectively. Measles caused 5 deaths, equal to a death-rate of 0.02, scarlet fever, 10 deaths (0.05); diphtheria, 22 deaths (0.11); enteric fever, 7 deaths (0.03); whooping-cough, 48 deaths (0.25); diarrhoea, 127 deaths (0.66); respiratory diseases, 392 deaths (2.04); phthisis, 218 deaths (1.14); other tuberculous diseases, 94 deaths (0.49).

The following table shows the birth-rate, death-rate, zymotic death-rate per 1,000 persons living, and infant mortality in Cardiff as compared with the rates in England and Wales during 1908, and with the rates in Cardiff during previous years:

	Birth-rate.	Death-rate.	Zymotic Death-rate.	Infant Mortality-rate.
England and Wales ...	26.5	14.7	1.29	121
76 great towns ...	27.0	14.9	1.59	128
142 smaller towns ...	26.0	14.0	1.26	124
England and Wales (less the 218 towns)	25.2	14.7	0.99	110
Cardiff ...	27.0	13.2	1.14	124
Cardiff (1907) ...	25.9	15.0	1.91	151
Cardiff (ten years) 1897-1906	31.4	15.8	1.98	145

MEDICAL INSPECTION OF SCHOOL CHILDREN.

A MEDICAL INSPECTOR OF SCHOOLS.—1 and 2. In an urban district with a population of 30,000, and where there are about 5,000 children in twelve schools, the medical inspection of the children who enter, and of those who are about to leave, would take quite two hours a day for three days a week during the school year. The remuneration for this should be at the rate of £150 per annum, based upon the following recommendation of the Subcommittee of the Medico-Political Committee of the British Medical Association:

That the remuneration of a medical inspector be calculated on the principle of a definite rate per working hour. That the school medical officer be paid at the rate of £50 per annum for an attendance of one half a school day per week, half a school day being defined to be two hours.

3. The Local Government Board does not sanction a whole-time appointment as medical officer of health at a smaller salary than £500 per annum. This would be a fair salary for a town of the size named.

4. It is neither customary nor necessary to "test the vision" in the case of children under 6 years of age, but in the case of children suffering from strabismus or other obvious visual defect it is usual to make an examination.

Obituary.

JOHN TAWSE NISBET, M.D., C.M. EDIN.,

LIVERPOOL.

We regret to have to announce the sudden death, in the prime of life, of Dr. John Tawse Nisbet, of Liverpool.

Dr. Nisbet was the son of a distinguished clergyman of the Church of Scotland, the Rev. Dr. Nisbet, of the Cathedral of St. Giles, Edinburgh. His mother, whose maiden name was Tawse, belonged to a family long settled at Stobsish, East Lothian.

Dr. Nisbet had a distinguished career in the University of Edinburgh, and graduated M.B., C.M. in 1884. He took the degree of M.D. in 1889, his thesis being commended. He was successively House-Physician in the Edinburgh Royal Infirmary and House-Surgeon in the Edinburgh Royal Hospital for Sick Children, and then established himself in Liverpool, where he was appointed Assistant Medical Officer to the Infirmary for Children, a position which he held for fifteen years. He was also Consulting Physician to the Children's Rest, an institution in which he was keenly interested. He held the rank of Surgeon-Captain in the Lancashire Hussars. Dr. Nisbet enjoyed a large and high-class general practice. His professional gifts were of a high order; these, combined with his kindness, geniality, cheerfulness, and self-sacrificing devotion to the interests of his patients, caused him to be beloved and esteemed in no ordinary degree. His end came with startling suddenness. He had often been told by those who knew him intimately that such incessant work as he undertook, with few if any holidays or times of relaxation, involved no little personal risk; but there was no reason to suppose that he was suffering from any serious disease, nor, indeed, that he was ill at all. On Saturday, February 13th, while he was visiting a patient, he was suddenly seized with faintness, and, though every possible means of resuscitation was tried, he expired in a few minutes by the bedside of the patient whom he had come to attend. The event was a pathetic, though in a sense an appropriate, ending to a singularly useful, kindly, and laborious life, devoted solely to the welfare of the sick and suffering.

Soon after settling in Liverpool, Dr. Nisbet married Miss McCardy, and he leaves a son and a daughter, both grown up. Dr. Nisbet was a great and general favourite among his medical brethren. His removal will be deeply mourned by his patients, who always found in him a faithful friend and adviser, and by a large circle of private and professional friends. The interment took place on February 16th, at Halewood Church, preceded by a service at Christ Church, Linnet Lane. A very large gathering of medical practitioners and others attended to show their esteem and regard for the deceased.

Dr. S. W. THOMSON, who succumbed on February 13th to an attack of post-influenzal pneumonia, will be greatly mourned by many friends and medical colleagues. He was peculiarly endowed with the power of gaining and returning affection. He was an Owens College man, and graduated M.B., Ch.B. in 1894. He had led a very varied life, but all his leisure was devoted to philosophical speculation, reading, and discussion. His thesis for the M.D. of the Victoria University, Manchester (1905), was a learned attempt to explain the activities of the nervous system in terms of electrical energy, a close analogy being drawn between the synapsis and the elements of a Leyden jar. In later years he had been working at an elaboration of this theory. He served with distinction in the Ashanti expedition for the relief of Coomassie, and was specially mentioned for saving life by sucking the wound from a poisoned arrow. For some time he was partner in practice with Dr. Vansbrough Jones, of Didsbury, and was universally beloved. Thereafter he made many voyages to Brazil and elsewhere, and was in great demand among the captains as a ship's doctor. He had lately been acting as Assistant Medical Superintendent at the Sandlebridge Epileptic Colony.

THE death is announced after a long illness of Dr. FRANK UTREN PURCHAS, of Newtown, Montgomeryshire. He was

born in Jamaica in 1861 and was educated at the Godolphin School, Hammersmith. He returned to Jamaica and subsequently resolved to enter the medical profession, and graduated M.B., C.M. in the University of Edinburgh in 1887, taking the degree of M.D. in 1890. Shortly after graduating he went as an assistant to Newtown, subsequently joining his former principal, Dr. Ferguson, in partnership. He was Senior Medical Officer to the Montgomeryshire Infirmary, in which he took much interest; he raised a fund to complete the equipment of the operating room and was an ardent supporter of a project to build a new infirmary. He was also Certifying Factory Surgeon and Parish Medical Officer for Bettws and Llanllwchaearn and Medical Officer for the Post Office. In 1891 he married the second daughter of Sir Pryce Pryce-Jones, by whom and by one daughter he is survived. His skill in his profession and the interest he took in public work related to it caused him to be very highly esteemed in the district in which he practised, where his loss will be much felt.

By the death of Mr. T. J. PATRICK HARTIGAN at the comparatively early age of 48 the profession has lost an able and energetic member. The son of an army officer, he spent his youth in India, whence he returned at the age of 17. He studied medicine at Galway, and was for some years Surgeon on the P. and O. and other steamship lines. After practising for a short time in Shropshire he settled in general practice at East Grinstead. In 1894 he became Medical Officer to the East Grinstead Workhouse and Urban District. Subsequently he was elected a member of the Urban District Council, of which a couple of years later he became Chairman. Not content with general practice in a quiet country town, Mr. Hartigan's ambition led him to take the Fellowship of the Royal College of Surgeons of England in 1899. While studying for these examinations at St. Bartholomew's Hospital he visited London daily, although continuing to practise at East Grinstead. Eventually giving up general practice, he devoted himself to dermatology, which he had studied in Vienna and elsewhere. Being appointed Assistant Surgeon and Pathologist to the Hospital for Diseases of the Skin at Blackfriars, he started practice as a skin specialist in Harley Street, and was beginning to do well in this branch of his profession, when his promising career was brought to a close. For the last two or three years his health had been failing, and he had been under medical treatment for renal disease which led ultimately to somewhat sudden heart failure. He leaves a widow and two young children.

WE have to announce the death of Dr. J. J. MURPHY, a well-known general practitioner in Dublin, where he enjoyed a very considerable practice for many years. He became a Licentiate of the Apothecaries' Hall in 1872, and in the same year obtained the licences from the Edinburgh colleges. He was very popular, and as a practitioner had the confidence of the public. He was twice married, his second wife being the daughter of the Right Hon. T. A. Dickson, at one time a prominent member of the House of Commons. He leaves a widow and five children.

MR. J. LESLIE FRASER, L.D.S., of Inverness, was well and favourably known to the profession in the North of Scotland. He was a welcome and honoured guest at all the meetings of the Northern Counties of Scotland Branch of the Association, seldom missing a meeting, his pleasant social qualities adding much to the success of our gatherings. For two years past he had suffered from repeated attacks of cardiac asthma. Last year he derived great benefit from a course of treatment at Nauheim, his friends fondly hoping that by taking things easy he might eventually be restored to his former robust state of health. An attack of cardiac distress, however, accompanied with uræmic symptoms, proved too much for an already weakened heart, and he passed away on the morning of February 12th, in his 47th year. Mr. Fraser had one of the largest dental practices out of Edinburgh, patients coming to consult him from long distances. As already indicated, Mr. Fraser was highly respected by the medical practitioners in the North of Scotland; he was a man of the most genial character, kindly disposed to all who were

in any trouble or distress; he will be much missed by a large circle of friends, who to his widow and children extend their warmest sympathy.

News has just been received from South Africa of the death of Dr. JAMES KEY, eldest son of Dr. Andrew Key, of Montrose, one of the senior members of the profession in the north-east of Scotland. After receiving his early education in Montrose, Dr. Key went to the Aberdeen Grammar School, later on going to Marischal College, where he graduated M.B. and C.M. in 1890. After assisting his father in Montrose for two years, he went to South Africa, and, on the outbreak of the Boer war, was among the first to take up arms on behalf of the Mother Country. He served throughout the campaign as captain in the regular army, and received the South African medal with three bars, as well as the King's medal. Dr. Key had the distinction of receiving Lord Roberts on the distinguished Field-Marshal reaching Bloemfontein. At the close of the war he was gazetted a captain in the South African Constabulary. He subsequently acquired a practice in Roopepoort. While studying in Aberdeen Dr. Key made a name for himself in sporting circles. He was a crack Rugby forward in the university team, and as a batsman his services were greatly valued in the university as well as the Aberdeenshire county eleven. He was 41 years of age, and leaves a widow and two sons to mourn his loss.

SURGEON-MAJOR THOMAS JOHN TUCKER, who died on January 27th, at his residence at Hindon, Wiltshire, was born in 1828, and received his medical education at Guy's Hospital. He obtained the diploma of M.R.C.S. Eng. in 1855, and in the same year entered the army as an assistant surgeon. He served first with the 10th Regiment during the Indian Mutiny, and was present when three native regiments mutinied at Dinapur on July 25th, 1857, and at the defeat of the rebels under Koer Singh, with the capture of Jugdespur in the following August. In February and March, 1858, he took part in the advance to Lucknow, and was present at the actions of Chanda, Umecurpur, Sultanpur, and Dura, and at the siege and capture of Lucknow. For his services he received the Mutiny medal and clasp. Subsequently he served with the 51st Regiment and retired in 1877 with the rank of surgeon-major.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Eugene Boddart, of Ghent, a young surgeon who had already won for himself a considerable reputation by his work, especially in the domain of urinary surgery; Dr. Henry Lamy, Physician to the Tenon Hospital, Paris, Director of Professor Chantemesse's laboratory, where he made researches on the action of the typhoid toxin on the nervous system, and on the mechanism of the renal secretion, author of articles on epilepsy, Graves's disease, and myxoedema, etc., aged 45; Dr. Van Ryn, of Brussels, General Secretary of the Belgian National League against Tuberculosis; Freiherr Franz von Preuschen von und zu Liebenstein, Professor of Gynaecology in the University of Greifswald, aged 64; Dr. G. Ruegenburg, of Bonn, a member of the Reichstag since 1903, and of the Chamber of Deputies from 1898 to 1907, in both of which assemblies he was a staunch defender of the interests of the medical profession, aged 68; Dr. F. Legge, Professor of Anatomy in the University of Cagliari; Dr. G. dell' Isola, Lecturer on Medical Pathology in the University of Pavia; Dr. P. J. Diakonoff, Professor of Surgery in the University of Moscow; Dr. J. E. Marques, sometime Professor of Clinical Medicine in the University of Coimbra; Dr. S. B. Rannett, formerly Lecturer on Orthopaedic Surgery in the University of Groningen; Dr. M. Tschistjakoff, Lecturer on Venereal Diseases at the Russian Army Medical Academy, St. Petersburg; and Dr. R. Rybalkin, Medical Director of the Department of Nervous Diseases in the Marien Hospital, St. Petersburg.

MESSRS. EVANS, GADD AND CO., of Bristol and Exeter, have issued, with the title *Drugs and Medical Requisites*, a price list, which, in addition, contains prescribing notes, an article on violet leaves in medicine by Mr. H. Wippell Gadd, a list of synonyms, and a note on the standardization of drugs.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL

The offices of the British Medical Association and of the British Medical Journal are at 429, Strand, London.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the Journal, etc., should be addressed to the Office, 429, Strand, London, W.C.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Zitiology, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, London*.

TELEPHONE (National).—

2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.

2630, Gerrard, BRITISH MEDICAL ASSOCIATION.

2634, Gerrard, MEDICAL SECRETARY.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

We would request correspondents who desire to ask questions in this column not to make use of such signatures as "A Member," "A Member B.M.A.," "An Enquirer," and so on. By attention to the request much confusion would be avoided. Correspondents are asked to write upon one side of the paper only.

KHOUK would be much obliged to any member who would suggest an anal instrument for an old lady, aged 70. Deafness has come on gradually, and is apparently due to advancing years. What she requires is some form of apparatus which would enable her to hear general conversation in a small room.

DENTER asks for advice with regard to a patient, aged 4, suffering from paresis of the right arm and leg, caused by falling on her head when 3 months old. The patient can use the arm for the coarser movements, and run about fairly well without much fatigue but with a slight limp; there is a slight dropping of the toes, and a considerable amount of eversion but very little shortening. He desires to know if any light instrument can be used to correct this, or would operative treatment be of more use, and, if so, at what age it should be done? The patient has a boot with iron support to calf and a spring to lift the toes, but this does not correct eversion.

GOAT'S MILK.

DR. COLIN CAMPBELL (Southport) writes: Would any of your readers very kindly inform me where I can obtain a healthy young goat in kid, and what would be a reasonable price? I want one badly.

LETTERS, NOTES, ETC.

A WARNING.

DR. OGIER WARD (73, Cleopside, London, E.C.) writes to warn medical men with regard to a man who applied to him, giving the name of Morris, for clerical work and bookkeeping. From information in the possession of the Charity Organization Society, it appears that he also goes by the names of Wallis, Watts, and perhaps Hart. His story with regard to his past employers appears, so far as it can be tested, to be untrue, and the references he gives are unwarranted. He is said to be tall, spare, active, looking about 30 years of age, wears glasses, and speaks rather jerkily.

PROPORTIONAL REPRESENTATION.

DR. G. CRICHTON (London) writes: In France a new electoral law is called for, and an important political party, in a manifesto just issued, makes a special feature of proportional representation. In the new Constitution of United South Africa the Parliament which will be created and will exercise sovereign powers over the different states is "to be elected by proportional representation, so avoiding the possibility of the tyranny of majorities." It is plain common sense that this method, which has been before the Associa-

tion for two years, should at the present juncture be carefully considered. It has been before the Annual Meeting on two occasions, and has been slurred over. The plan of single-member constituencies was introduced into Parliamentary elections at the instance of the late Marquis of Salisbury twenty years ago, and has from the first proved most unsatisfactory. The recent scheme for elections to the Central Council adopts this plan, about to be discarded in politics. Is it too much to ask that committees of Divisions, especially those members who are to be Representatives, should take the trouble to comprehend the scheme? It is really very simple in its working. A model election might be arranged at trifling cost. A clear statement of the minds, the opinions of the members of our great Association, is far from being a matter of indifference. Otherwise, men elected on no clear ground will act, if at all, indecisively; and as there is a constant change of personnel on our Councils, so our policy will be unstable, depending on their private opinions, and not, as it should, on clear principles thoroughly debated beforehand. An explanatory pamphlet is issued by the Proportional Representation Society—price 1d.—23, Martin's Lane, Cannon Street, London, E.C. Surely every secretary who has an intelligent interest in the working of our machinery will supply his committee with these.

AN ALLIED CURE FOR CONSUMPTION.

MR. H. OSBORNE O'HAGAN (Casa del Mare, Cabbe Roquebrune, Alpes Maritimes, France) writes: "May I be permitted to correct an impression that may have been given in my letter which appeared in your issue of January 16th last? I spoke of the rights I had acquired for the Churchill treatment without explaining that these rights were in connexion with the inhalant "spirone," and I did not include the Churchill preparation of hypophosphites, the full advantages of which had already been disclosed. The inhalant alone was the secret treatment which was claimed as a specific for all inflammation in connexion with the lungs, throat, nose, etc.; but foremost in his treatment of tuberculosis stand the hypophosphites, although Dr. Churchill stated in his works that the inhalant was such a valuable adjunct in such cases as to double the success both in time and in the number of cases. It is only recently that I fully realized this, although in tuberculous cases I have always stipulated also for the use of the hypophosphites. So long as the physician has information of the particular hypophosphites to be used he does not want the formula, and as to the inhalant the formula for that is now at the disposal of the medical profession. It is essential that the hypophosphites should be pure, and to secure this the late Dr. Churchill placed the preparation of his hypophosphites with Messrs. Swann, the eminent chemists, of Paris, who hold the sole rights thereof. I am anxious that it should be understood that in advocating the use of hypophosphite and spirone I am in no way interested in Dr. Churchill's particular preparations of the hypophosphites."

MEDICAL FOOTBALL.

THE match between the United Hospitals and the Royal Navy, played at Richmond on February 10th, resulted in a win to the Navy by eleven points to three. The Navy had a fairly representative team, but the Hospitals suffered very severely from the absence of the London Hospital backs. The most notable features of a game remarkable for the excellence of the play was the particularly clever run by which Cooper scored for the Navy just after half time, tricking his opponents on three several occasions by feinting to pass and continuing his run, and the really brilliant co-operation between the Hospitals' representatives which resulted in Mullins securing a try shortly before the finish of the game.

The big scores to which the London Hospital fifteen are rapidly becoming accustomed were increased, when playing against St. Mary's, in the Inter-Hospital Challenge Cup-Tie; the London secured a victory by thirty-nine points to none.

In the first round of the Inter-Hospital Cup-Tie at Richmond, King's College Hospital, after making a good fight in the first half, were beaten by St. Thomas's Hospital by three goals and three tries to a try.

The London Hospital defeated Charing Cross at Richmond by thirty-two points to nil. Charing Cross, however, though obviously overplayed, made a capital defence, and on one or two occasions seemed as if they would succeed in stealing a try from their opponents. Lindsay and Henle, as half-backs for the London, were largely responsible for the heavy scoring, giving the three-quarter line all their opportunities.

A hotly-contested match on the same day between University College Hospital and Guy's resulted in a victory for the latter side by one try to nothing.

Play on February 15th between the Middlesex Hospital and St. Thomas's in the second round of the Inter-hospital cup tie ended in a draw. It is expected that the match will be replayed early next week. The winner has a bye in the semi-final round and will enter the final. Play throughout the match was bad, the best feature of the game being the really good defensive work by Penny, who won his blue for Cambridge. During the second half of the game Hunter had to retire owing to a damaged collar bone.

The most interesting of next week's fixtures is the match between the London Hospital and Guy's (semi-final), which will take place on Wednesday at the Richmond Athletic ground.

THE LIMITATIONS OF A PURIN-FREE DIET.

MIDDLE-AGED writes: Having been on the above régime for over three years, as well as one of my family, I can say that, as far as people of ordinary health are concerned, it is quite feasible. Previously, though in good health from the insurance point of view, I was a frequent sufferer from rheumatism, headache, dental troubles, tendency to constipation, and short febrile attacks resembling influenza. For two and a half years now I have been quite free from all these annoyances, and even ordinary coryzas have been much less frequent, and last from one to two days only. The influenza-like attacks were, to my mind, due to what Dr. Haig calls collaemia, and at the beginning of my change of diet, when I was also taking salicylate, a similar brief attack supervened, brought on, I presume, by the drug.

I have never brought myself consciously to propose such a diet to a patient, because the good results are slow in developing, and because I consider that serious consequences may attend the too sudden withdrawal of all stimulating foods, such as meat, etc., and beverages, such as tea, coffee, cocoa, etc.; to most people the diet seems to offer so little that is palatable that they would rather continue in their present state and be subject to frequent malaises. However, one other relative has gone in for the diet with good effects, and the example of my well-being is gradually affecting the mode of living of many others who have the opportunity of seeing me frequently.

Dietary for Three Days for a Person Weighing 150 lb. net, aged, say, 40.

FIRST DAY:

Lunch (12.30 to 1).—Green vegetables, baked potatoes and butter. Stewed figs, ½ pint junket. 2 oz. grated pine kernels with cream (whipped).

Dinner (7 or 7.30).—Biscuits, butter. 1 oz. grated cheese or curd. Light pudding. Cream, stewed fruit.

SECOND DAY:

Lunch (12.30 to 1).—Green vegetables, potatoes with butter and cheese sauce. Fruit tart cream, ½ pint milk.

Dinner (7 or 7.30).—Biscuits, butter, two boiled eggs. Milk-pudding, containing ½ pint milk. Stewed fruit, cream.

THIRD DAY:

Lunch (12.30 or 1).—Green vegetables or salad, potatoes and butter. Pudding or cutlets containing 2 oz. of nuts. Stewed fruit, cream.

Dinner (7 or 7.30).—Biscuits and butter. Cheese soufflé or cheese omelette. Cream, stewed fruit, roast chestnuts.

Daily quantities: ½ pint of cream, 2 oz. of butter, 2 to 3 oz. of biscuit, 3 pints of milk, or 6 oz. of grated nuts, or 6 to 7 oz. of cheese, or the latter three in combination in varying quantities, all of which to be made for any eggs.

Remarks.—If a breakfast is required, milk or milk and biscuits, the above meals being reduced by the amount taken at breakfast. Unfertilized eggs are preferable to fertilized. Olive oil is useful where it can be taken, either neat or in salad according to season; raw fruit when in season, dried fruits in winter, stewed if preferred; nuts can be incorporated in many puddings, as also milk or milk powder.

Cheese can also be incorporated in many ways; macaroni cheese would be a substitute for biscuit, butter, and cheese. I should say that any person of ordinary health and under 35 could make the change. In those of more advanced years and chronic invalids I doubt whether the change could be made at all. In any case I would suggest waiting for a temporary restoration to normal health.

In my case I do not feel the loss of any of the foods I have abandoned, and even alcohol has no charms. Many may argue that life under such circumstances is not worth living, but it must be conceded that immunity from small ailments brings with it the feeling that grave illnesses, which, after all, always are the results of severe colds or gastric indulgences, are no longer possible in my case. In this category I would place appendicitis, enteric, pneumonia, bronchitis, all acute rheumatic affections, and possibly even Bright's disease, diabetes and tuberculosis.

SC LE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under	0 4 0
Each additional line	0 0 6
A whole column	2 13 4
A page	8 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at Postes Restantes addressed either in initials or numbers.

A Clinical Lecture

ON

CHRONIC SPINAL MENINGITIS:

ITS DIFFERENTIAL DIAGNOSIS AND SURGICAL TREATMENT.

By SIR VICTOR HORSLEY, F.R.C.S., F.R.S.,

SURGEON TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND
EPILEPTIC, AND CONSULTING SURGEON TO UNIVERSITY
COLLEGE HOSPITAL.

THIS afternoon I desire to deal with a subject on which as yet I have published nothing, but on which I have been threatening to publish something for the last ten or twelve years. It is the question of operating in a group of cases which are apparently fairly common. For instance, without much trouble Dr. Grainger Stewart has collected (November, 1907) the records of 21 cases which I have operated upon. So it is a class of case which is met with fairly frequently, certainly more commonly than tumour of the spinal cord. It presents the same symptoms—except certain minutiae—as tumour of the spinal cord; indeed, these cases have usually been diagnosed as tumours of the spinal cord and transferred to the surgeon, and yet they are not tumours at all. They are cases of chronic spinal meningitis, the causation of which has yet to be finally determined. They yield to surgical treatment when ordinary medicinal treatment has failed. I do not mean to say that they all yield to surgical treatment—I wish they did—but so many do that it is quite clear that earlier diagnosis would have saved, in my opinion, the majority, if not all, of the cases.

Like all these subjects when a new clinical condition is recognized, many things are brought in under the same heading which do not belong to it at all; in fact, the very expression I have used—"chronic spinal meningitis"—would suggest to you at once that such a vague clinical expression must include a number of conditions which do not owe their existence to the same cause. The class of case I refer to you will recognize from my having said that they resemble tumour of the spinal cord. They are those in which an adult person—because I have only one case below the age of puberty—begins to complain of pain and progressive loss of power in the legs, with it may be also slight kyphotic curvature of the spine, and develops ultimately a progressive paraplegia that runs through the ordinary course and terminates fatally.

The first clear case of this kind which I met with was some ten years ago, when Sir William Gowers referred to me a gentleman who had complete paraplegia, who had a distinct but a very slight kyphotic curve of the dorsal vertebrae, and who, Sir William Gowers thought, was probably a case of caries and secondary paraplegia, which was commencing when he first saw the case but which was very advanced when the patient came under my care. I confess that, for my own part, I did not accept the diagnosis of caries, but I was unable at that time to substitute any other for it; and, inasmuch as the patient had compression paraplegia, I, of course, agreed to operate, from the general point of view of relieving the compression. But when I came to operate, I found that instead of the neural canal being narrowed by disease of the bone, it was narrowed because the theca of the cord was enormously distended and filled up the lumen of the canal. Further, on opening the theca, instead of finding a tumour inside, compressing the cord, I found nothing but a very considerable excess of cerebro-spinal fluid, and a cord that was rather shrunken. Being anxious lest there might be a tumour other than at the point exposed, I explored with a probe up and down the neural canal for a distance of 5 or 6 in. but found nothing. But inasmuch as the localization diagnosis of the upper limit of compression was quite clear, the symptoms corresponding to a lesion at the sixth dorsal root level, it was obvious there was nothing more to be done than to close the wound, and this I did. The patient made an ordinary recovery and gradually began to improve, until now, from having retired from the city, he has gone back to the city and is engaged in Stock Exchange work.

Such was the first case of the kind I have seen, and it attracted my attention very forcibly, because in the first instance an accurate diagnosis was completely wanting; and, secondly, because here was a condition which was getting worse under antisyphilitic remedies and every other kind of drug treatment, but the progress of which was completely stopped by laminectomy, freely opening the theca and washing out with mercurial lotion. The patient, as I say, got well, went back to work, and has remained well.

Without wearying you with details, I may say that I have seen a relatively large number of such cases, on most of which I have performed laminectomy and subdural mercurial irrigation. All the cases also which have been referred to me have been diagnosed at the time I have received them as tumour of the spinal cord or disease of the vertebral column. But naturally during ten years one becomes more wary, and I have for a long time shown that there are certain features in these cases which should lead to their being recognized as cases of chronic spinal meningitis and not tumour. That is the position which now deserves discussion. I would have raised this question long ago but for the fact that inasmuch as the first twenty operations were not followed by death, no anatomical examination of the condition was forthcoming.

In 2 cases, however, we have obtained the spinal cord. In one the operation had been completed, and six weeks after the wound healed the patient died suddenly from syphilitic myositis—probably of the atrioventricular bundle. In the other no operation was done, and the patient succumbed to the paraplegia. In both a meningo-gliosis (sclerosis) was found. The spinal cord, so often seen at the operations to be shrunken, was markedly contracted in a tabes case, and exhibited microscopically typical glial sclerosis.

I shall not take up your time by going into a critical examination of the accounts of chronic spinal meningitis which have been given by the classical neurological writers, although the clinical investigation of these cases needs a great deal of further work to render the description in the textbooks definite and practically accurate. The real matters of interest relate to the circumstances under which the condition arises, which can be relieved by surgery, what is the proper surgical treatment, and what is likely to be the result.

Of recent years similar cases have been described in America and in Germany. The first actually published¹ was one under the care of Drs. Spiller and Nusser and operated upon by Dr. Edward Martin, the patient making an excellent recovery. In April, 1907, Professor F. Krause made an interesting communication² to the German Surgical Society, and described 6 cases (out of 22 referred to him as tumour cases) in which the hydrops and meningitis serosa spinalis were demonstrable as the cause of the paraplegia. The condition was determined in 2 of the cases by *post-mortem* examination. Krause quotes Dr. H. Schlesinger,³ who described the condition anatomically in 1898 in a case of paraplegia with necropsy. Professor Oppenheim,⁴ who had examined Krause's cases clinically and treated them medically, also regarded the disease as an extensive meningitis.

Since this lecture was delivered (July, 1907), there has been published a further brief communication from Dr. Spiller,⁵ in which he again draws attention to the case published in 1903, and, after saying that the condition cannot be distinguished clinically from tumour of the cord, advises earlier surgical intervention.

The cases of parasitic and other cysts referred to in his argument with regard to the mechanical conditions of pressure do not elucidate further the nature of the cases under discussion, and therefore, in the short time at my disposal, I shall confine myself strictly to what Spiller calls "circumscribed spinal meningitis."

It will now be evident how closely these cases resemble instances of tumour of the spinal cord. I might take any one of the series of notes which I have before me and outline it. Let me take the last which we had, and which was put down on the notes here as "Spinal tumour, extra-medullary." That is the diagnosis from the medical side, and it is as recent as July of this year (1907). So you see that up to the present time our diagnosis requires a good deal of perfecting. This patient is now in the convalescent home, so I regret I cannot show her to you.

She was a single woman, aged 40, without anything particular in the family history. There was a previous personal history of anaemia, but nothing in the nature of a serious illness until 1901. For the last ten years she had very heavy work as a dressmaker, with much standing and kneeling. Six years ago she had a severe attack of influenza, when she was ill for a month with pains all over her; and very soon afterwards she began to complain of pains in the right loin, worse on movement, and a feeling as if the muscles of the thigh were tightening. In drawing your attention to the fact that this case is referable to influenza as the probable cause of the meningitis, I would remind you of the cases of meningitis described in 1890 and 1891 by Horatio Wood of Philadelphia, because several of these cases have appeared now to be residual cases of such spinal meningitis as was originally described by Wood. The pains spread gradually to the front and back of the right thigh, and during the last twelve months they have caused painful cramping and twitching of muscles of the right leg. The right toe often cocks up involuntarily with the pain. Ultimately, therefore, the pain in this case has affected the whole of the right leg, having begun in the right groin. It involves a diffuse area, one which is supplied by several nerves; there is no particular nerve-root distribution which is involved, but the whole limb is in pain, and can be shown on a chart. I invite your attention to this point first, because this I consider to be the most valuable among the minutiae which serve to distinguish these cases from cases of spinal tumour. A tumour of the spinal cord commonly exhibits the symptom of pain as localized to one nerve root; it does not give you, as a rule, areas of pain which necessarily involve many nerve roots. If spinal tumour cases are examined minutely it will be found that in the large majority of them the pain begins at or near one nerve root, and to the distribution of that spot the patient will chiefly ascribe his or her pain. This chronic spinal meningitis, on the other hand, being a general condition, tends to affect diffuse areas painfully, exception being always made for the upper limitation of anaesthesia. (See below.)

We will now pass on. For two years or more there has been besides this pain marked tightness and numbness of both thighs, as if they were made of marble. During the last two years there has been slight dribbling on micturition, and during the same period the pain has been so severe that it limited freedom of walking, so that the patient could only take one step at a time in going up and down stairs. Four weeks ago there was severe pain in the small of the back. Many of these patients describe a painful area in the spine without necessarily exacerbation on movement. On admission the patient was a very stout, healthy-looking woman, with no indication of disease in the circulatory or alimentary systems, nothing abnormal in the cerebral nerves, or cranium or upper limbs. The pupillary reactions were equal and normal. So to the middle of the body there was nothing discoverable. There was slight wasting of the whole of the right leg and general weakness of the whole of the right leg—see how universal these symptoms are—some eversion of the ankle with weakness on dorsiflexion of the foot, and some extension of the hip. There was very considerable alteration of sensation. The alterations of sensation were these: that she had relative anaesthesia of the whole of the right limb and of the right hypochondriac region, the anaesthesia being to all forms of sensation as well as relative analgesia. The coexistence of analgesia and anaesthesia I always think is an extremely serious point to bear in mind in all spinal cases, because it carries with it the assumption that the spinal cord itself is centrally involved in the lesion, whatever it be. With regard to the deep reflexes, the knee-jerk was markedly diminished on the right side, present on the left, but both were, on the whole, diminished. I will come back to the question of the knee-jerks later. As regards the superficial reflexes on admission, the plantar reflex on the left side is flexor, but it is less definitely so on the right. When I examined her later I found she had an extensor response. The abdominal reflexes were present on the right and left. With regard to the sphincters, I have said already that there had been dribbling after micturition. There should have been added there a most important point, namely, that there was no trophic lesion whatever in the skin, nor apparently any tendency to

decubitus. On testing her with pilocarpin to map out the deficiencies of the secretory system, for comparison with the tactile anaesthesia, according to the methods which I have demonstrated as useful for twenty years, there was found a very marked parallelism.

That is the story of a typical case. On operating at the level of the dorsal segment a marked degree of chronic meningitis was found and relieved. But such extremely marked localization, one side being apparently chiefly affected, would of course lead to the assumption that certainly one half of the cord must be primarily affected, and might carry with it the further assumption that the lesion was more probably a tumour than general meningitis. I wish to draw particular attention to this point at this stage, because all these cases, if you look into them carefully, present a certain degree of unilaterality by the time they come under our direct notice. In further illustration of this point I show you sections of the spinal cord of an interesting case, which was not treated surgically and died in the hospital a short time ago. In these specimens you will notice that there was a condition of things exactly parallel to what I have frequently observed—namely, a sclerotic condition of the cord, beginning below and creeping up the cord. As a matter of fact, all the lower part of the cord shows only the endogenous fibres preserved. When you look at it with the lens you see that the ascending degeneration has affected one side notably more than the other. Consequently, although it is put down as universal disease, it nevertheless has a distinctly unilateral pathological locus. So the fact that we find that most of these cases have a unilateral origin must be recognized at the onset, because it must not prejudice our opinion. Probably we are naturally inclined, when there is marked unilaterality in the symptoms, to jump to the conclusion that it must be tumour. But now, after this series of cases, it must be recognized that that is not the fact—that it may equally be this condition of chronic general meningitis.

Now as regards further details. First the quality of the pain. As I said before, pain is felt in one limb to begin with, and then it spreads to the other limb, and then up the back. It is generally said by the patient that the pain is in the substance of the limb, and it feels in the majority of cases like a tightening or drawing up, and most patients complain specially of the sensation of tightness. And while speaking on that point I may also draw your attention to the fact that sometimes they have in addition the typical girdle tightness or compression, a feeling as of a band around the middle of the body. With regard to the degree of the pain, it may be similar to that in tumour cases, in that it may be so severe as to prevent sleep.

With regard to ordinary sensation, we will refer to this under the heading of "hyperaesthesia and anaesthesia." With regard to hyperaesthesia, this patient whose case I have just recounted to you on some days had very marked hyperaesthesia over the whole leg, a condition of things which I have never seen in a tumour case, in which at the outset there would be either a marked zone of hyperaesthesia at the upper limit of the anaesthesia, or a similar area corresponding to the nerve root or roots on which the tumour was situated. But when there is hyperaesthesia over a large area, it ought always to suggest to you that a number of nerve roots or their central representation mechanisms are in a state of irritation, at any rate in a state of physiological hyperexcitability. So that the distribution of the hyperaesthesia in these cases is an important symptom as helping to correct the diagnosis.

With regard to tactile anaesthesia, none of these cases that I have seen yet have had absolute anaesthesia; it has always been relative, and sometimes it has been present only to a slight degree, though extending over a large area. Microscopically, in neither of the two cases in which we have been able to obtain a *post-mortem* examination so far were the nerve roots much affected. So it is easy to understand that there may be widespread paraplegia, and yet no absolute anaesthesia anywhere. Nor is there dissociation, for as this is a general affection of the roots altogether, all the fibres are affected, and therefore all forms of sensation—touch, temperature, etc.—are affected in greater or less degree.

Next, as regards efferent phenomena. First, with regard to movement. How do these patients become paralysed? They become paralysed first by a gradual sense of weakness coming on in the whole leg. You know that is a very common description given to you by patients who become paraplegic from tuberculous caries, because in that condition you get a kind of ischaemia of the spinal cord as a rule, and the whole machine, as it were, becomes weak, the conductivity of the whole cord becomes impaired, and therefore the patient says the whole leg is weak. So it is with these cases, where there is a general condition affecting the spinal cord and its roots, naturally the symptoms are grouped *en bloc*. As can be seen from these notes of the cases, a localized extra weakness of one joint, as for instance the ankle or the hip or the knee, may often be seen, but no restricted root paralysis—that is to say, paralysis of groups of muscles served by any one root. The general loss or diminution of the action of one joint involves the decadence of several segments of the spinal cord. Thus a gradual weakness which develops until at last the patients cannot stand. In a certain number of cases, even in a comparatively early stage, they complain of spasticity. So that some of these cases undoubtedly are diagnosed as instances of lateral sclerosis—that is, the old idea of lateral sclerosis; and when you come to examine the spinal cord in a very severe case you will find there is not only a lateral sclerosis, but a general sclerosis throughout the cord. The explanation of the sclerosis I will come to later.

With regard to the other efferent phenomena, I have already referred to and demonstrated that secretion is proportionately paralysed with the advance of the paraplegia. With regard to the vasomotor system, as a rule these patients show no vasomotor phenomena, quite unlike a bad case of compression paraplegia from caries or tumour, where vasomotor phenomena are more often observed. One limb may become oedematous, the joint may fill up with fluid—a so-called myelitic arthritis—and where at one stage the part may be crimson in colour, and as the paraplegia develops it may change into pallor, and, finally, in the last stage there may be obvious vasomotor contraction extremely marked with a shrunken dry skin. These meningitic patients do not present this picture at all; their skin looks very normal, and, as I said before, they show no tendency to trophic disturbance. Possibly at the very end they ultimately develop bedsores, like other paraplegics, but they have not the striking tendency to decubitus that an ordinary case of localized compression of the cord has. Before passing from the question of sensory troubles, especially in connexion with the nerve roots, I must refer to one private case which illustrates very strikingly the connexion between affection of the roots and this general affection of the membranes of the cord. The case was that of a lady, whom I saw with Dr. Ferrier originally, and who had complained of a severe pain in the heel—that is to say, in that branch of the posterior tibial nerve which supplies the skin of the heel. This pain was for many years treated as a functional pain, and the unfortunate family differences which followed only emphasized once more the extreme necessity of caution in diagnosing functional disease. One day she suddenly developed a peculiar outbreak of herpes in the distribution of the first and second lumbar roots—that is, a definite root distribution; and then it was naturally thought that the posterior tibial trouble was a peripheral neuritis. When I saw her with this herpetic eruption it was quite obvious that she had what appeared to be an affection of the whole nerve supply of the limb, but I did not recognize at the time that she was one of this class of case. However, the pain was so great and disabling that I suggested dividing the posterior roots of the first and second sacral nerves. This was not accepted by those in direction of the case, and for two years this patient went on, gradually walking less and less, until at last she was practically sitting in a chair all day long. Still, she had no paraplegic symptoms of the ordinary kind. It was then decided that she should be operated upon, and accordingly I exposed the theca of the spine over the lower end of the lumbar enlargement, in order to divide these two roots. As I then found the theca enormously distended, of course it was apparent that the case must be one of chronic spinal meningitis. On opening the theca a great rush of cerebro-spinal fluid occurred, the lumbar enlargement and

the commencement of the cauda equina were covered with thick yellowish-white matted arachnoid, and yet, as above stated, the pain was limited to the first and second sacral area, and the herpes to the first and second lumbar. Thus, the intermediate roots apparently had not suffered sufficiently to cause symptoms. I divided the posterior roots of the first and second sacral nerves, and then followed out the treatment I advise in these cases, and irrigated out the subdural space thoroughly with 1 in 1,000 sublimate solution. She made a very good recovery, and now she walks five miles at a time, and has, of course, lost her pain. It is now three and a half years since the operation was carried out, and she is apparently in perfect health, a position which is, perhaps, partly due to spinal mercurial inunction, which I have had continuously carried out since the operation. But this is the only case of the whole series I have seen in which there was a herpes, in which there was any evidence of posterior ganglionic affection, or any evidence of such minute root localization, and I only dwell upon it because it is such a striking illustration how in these cases we can be deceived.

Now we come to the question of the part of the spinal cord affected in this condition. This certainly is a very interesting question. The two cases I have used as illustrations obviously began in the region of the cauda equina, and in the large majority of these 21 cases the mischief apparently began all over the lower half of the back of the cord, and the large majority of them, I find on going over the notes, have (in consequence of the need of exposing the highest segment of cord symptomatically involved) been operated on at a point somewhere between the fourth and ninth dorsal—that is to say, in the mid-dorsal region. This is interesting, because, of course, we know that for one reason or another the mid-dorsal region has been, certainly for seventy years, recognized to be the usual seat of so-called transverse myelitis—at any rate, it has been referred to that region without any explanation being forthcoming. Whether it commences—like this case, for instance, which begins about the lower part of the lumbar enlargement and gradually goes up the cord—or whether it attacks the lower half of the cord simultaneously, will probably not be found out for a long time. But, however that may be, by the time the case is referred for operation, the exploration must begin in or just below the mid-dorsal region, because in the majority of these cases the zone of anaesthesia extends from the sixth to the eighth dorsal nerve root.

With regard to the age of the patients, I have already said that, with one exception, they were all adults. This question of age has a very important bearing, first on the question of the causation of the mischief, and, secondly, on the prognosis. I will therefore deal now with these two points. We will speak of prognosis first, because that is relatively an easier point. As we have to deal with a chronic inflammatory condition, the prognosis simply depends on the usual rule, that if a patient is below middle life or at middle-life recuperation is likely to be very good; if beyond middle life, it is likely to be very poor. The oldest case which I find I have operated upon was a private patient, a lady who was 60 years of age, and I am sorry to say she did not improve in the least. It was a very bad case; there was a great deal of pachymeningitis, and there was a depressing history of congenital disease. She only had one brother alive and "healthy." One brother had died of locomotor ataxy, and a sister, whom I saw, suffered severely from combined syphilitic sclerosis, and so on. I believe the fact that she did not improve was entirely due to her age. Turning now to the next point—namely, the cause of the condition—I have said that there is a considerable excess of cerebro-spinal fluid in these cases, and have referred to the thickening of the arachnoid and the matting of the nerve roots. Before we discuss further the pathological conditions, I ought perhaps to make reference to the collection of cerebro-spinal fluid in the neural canal as a clinical fact, and discuss with you whether it has any bearing on these cases. The cerebro-spinal fluid, of course, is secreted by the lining membrane of the cerebral ventricles, by the lining surface of the choroid plexus, and it is secreted at a rapid rate. Although it is secreted under pressure, it is thus manufactured quickly, and if the pressure is relieved by a little trephine opening connected with the

ventricles or other part of the cerebro-spinal system, it escapes in very large quantity. There are several other points connected with the physiology of the cerebro-spinal fluid which are of interest. The ependymal epithelium, which is flat in the ventricles, becomes columnar at the commencement of the aqueduct of Sylvius under the posterior commissure, and this fact, as Professor Dendy has shown, applies to all animals, and is especially marked in the mouse and animals as low in the scale as that. So it would seem to have some physiological significance, and he suggests that the cilia of these epithelial cells serve by accelerating the circulation of the cerebro-spinal fluid downwards. Of course the cerebro-spinal fluid as it is being secreted must be got rid of; it must flow out of the ventricles, and must pass into the cavities of the body. It has been shown that as it is manufactured high up, under positive pressure, it finds its way out along the lymphatics along the course of the nerve roots. That it has this circulation in the cord is proved first by the injection of coloured fluids into the ventricle, and also by such very interesting pathological cases as the one published last year by Dr. Barnes, where a growth in the ventricle was disseminated all the way down the central canal, showing that the virus was gradually carried down along this natural highway, as it were, by the stream of cerebro-spinal fluid.

As regards the spinal cord, we find that in these cases there is a large collection of cerebro-spinal fluid around the cord, and it is under great pressure, because in the first place it distends the dura mater, so that it almost fills the canal, and there is no impulse in the theca when it is exposed for laminectomy. Instead of the theca rising and falling with respiration and also indicating the pulsation of the heart, there is no movement in it whatever. When you open the ballooned theca, the fluid jets out, and then, when the whole thing collapses, you can see that there is a normal active movement of the cord; so that, at any rate, by the time these cases come to operation it is obvious that this physiological relationship of the cerebro-spinal fluid has become very abnormal, and that instead of having a proper circulation you have stagnation. I do not want to push this point too far, because we know so very little about it. We know nothing from the experimental point of view beyond the effect on the spinal cord of persistent stagnation or accumulation of cerebro-spinal fluid, but it is suggestive. And, seeing that these patients who do improve may improve so markedly simply from the free opening of the theca *plus* washing out—the effect of which I will discuss presently—it is very difficult to get away from the idea that this pressure does play an important part, and that consequently some of the benefit of surgical treatment is to be attributed to getting rid of such pressure.

The spinal cord, being subjected to this pressure, necessarily must undergo some ischaemic changes; and here we are in a very great difficulty, because we have no pathological material to enable us to say whether the changes which we can find in the only two cases which have died during these years are to be looked upon as truly representative because they were both cases in an advanced degree of the disease.

Causation.

That brings me to the next consideration—namely, the causation of the meningitis. In one of the cases just referred to certainly, and in both to some extent, there would be no doubt that syphilis was the cause; and, under those circumstances, one would say naturally that the sclerosis of the cord which was so very clear (see below), was a primary syphilitic sclerosis.

The point of chief interest is the condition of the cord in an average case. In every case when the theca has been opened and fluid allowed to escape the cord has presented a shrunken appearance, and once a slightly yellowish tinge. I have never operated upon an early case, except the one I referred to in which there was herpes, and there the matting of the arachnoid precluded an opinion as to the condition of the cord. I show you here the cord of one of the two cases referred to above, a man who was in this hospital, and on whom I operated some time ago. He had recovered from the operation and was commencing the usual improvement, when he died quite suddenly. The immediate cause of death proved to be the common event in cases of chronic syphilis—

namely, syphilitic disease of the atriocentricular bundle of the heart. In this case the cord presents a remarkably flattened appearance, and on examining the sections with the lens there is seen a definite sclero-gliosis all round the periphery of the cord. In this case, I think, all the columns are universally affected except in the cervical region. The nerve roots themselves are very slightly attacked, and therefore the incoming fibres of the column of Burdach are not much affected, but the fibres of the column of Goll are particularly. Therefore this case, at any rate, was not simply an instance of pachymeningitis, but pachymeningitis combined with a certain degree of sclero-gliosis of the cord. It is quite possible that this was the pathological condition in the majority of the cases I have seen and operated upon, but it is impossible with the present means at our disposal to speak positively.

Since the difficulty just experienced of discussing accurately the pathology of these cases is due to the fortunate rarity with which laminectomy ends fatally, I may fitly conclude by describing their treatment. In every instance all these cases have been liberally treated with drugs, and have had the most conscientious anti-syphilitic treatment when referred for surgical care, and yet they have steadily gone downhill. This, by the way, might be advanced as an argument that they cannot have had their origin in syphilis. Although, on my own part, I think a number of them are not actually syphilitic, some of the cases certainly are, and, as so constantly happens in syphilis of the nervous system, resist all treatment not directly applied by surgical intervention.

On the question of syphilis, I said earlier in the lecture that though this chronic meningitis was a disease essentially of adult age, there was one case I had treated in which the patient was not an adult, namely, the instance of a boy aged 12, who was admitted into the National Hospital under Dr. Beevor three years ago. His history was that he had a rather rapidly oncoming difficulty in walking, with cramps in the right leg, followed by weakness, and then in the left leg. Later the legs jumped, but there was no girdle sensation and no sphincter trouble. When he was admitted he also had a slight degree of nystagmus, which was a cerebral point. He had spastic paresis in the arms and legs, slight loss of power, and so on. It therefore seemed to be a definite case of high affection of the spinal cord, and the nystagmus was the only point which might have led one to hold one's hand. But, of course, nystagmus in a child, especially with a slight visual defect, was not enough to establish a contrary diagnosis or one of cerebral complication, and when I came to expose the theca I found it was a typical case of chronic meningitis, the theca being notably distended and a large amount of cerebro-spinal fluid liberated. The cord appeared normal, and on examination of the posterior median fissure nothing abnormal was found. He went out greatly improved. I believe that was a case of congenital syphilitic origin (cf. Gilles de la Tourette). But the record of causation is like much clinical work, unfortunately, in being the expression of beliefs rather than actual scientific fact. For my own part, since so very few of these patients have suggested traumatism as a cause, it is not a likely one, and, as Oppenheim particularly states, such serious meningitis is not a sequela of concussion or railway spine. Then when we come to think of other kinds of chronic specific inflammation we shall conclude, I believe, that a certain number of these cases are gonorrhoeal. I am quite ready to admit that we have not proved cytologically or bacteriologically that the cerebro-spinal fluid contains either excess of lymphocytes or gonococci, but as regards excess of corpuscles, that is not a necessary concomitant when we think of gonorrhoeal arthritis. Therefore the cytology of the affection is of less importance, and, as regards the bacteriology, great difficulties exist in tracing the gonococcus. I regret that I have no direct evidence to substantiate my view, and the only point I can adduce is that infection with gonorrhoea occurred in several cases relatively a short time before the occurrence of the spinal symptoms and in the absence of other infections.

Treatment.

Now for the detail of this surgical treatment. I have already suggested to you in the remarks made earlier that

it consists in simple laminectomy, opening the theca, and washing out the theca with a mercurial lotion. Here we enter at once on the general and interesting question of notable benefit attending the free opening of the so-called serous spaces and washing out with some antiseptic, because I suggest the parallel of this surgical treatment of spinal meningitis is the well-known surgical procedure of opening the abdomen to cure tuberculous peritonitis. I believe there is no risk in washing out the theca with strong solutions of mercury, even up to 1 in 500 strength, though I have only used that strength once or twice. Still, I should not have any hesitation in using it at any time where there was much exudation in the arachnoid, following it up with 1 in 2,000, and leaving in some of this strength when closing the wound.* The skin wound, I think, should be completely closed, not drained. I used to sew up the theca, my object being to arrest the escape of cerebro-spinal fluid into the wound. I have now given that practice up in almost all cases, because in the first place I found wounds healed as quickly, and there is as a rule no greater escape of cerebro-spinal fluid, so that that reason for suturing was not a very important one. Undoubtedly, too, there is less discomfort to the patient afterwards—namely, less tendency to headache and less tendency to the temporary praxia and tachycardia which laminectomy cases not infrequently show. But I have also come to believe that allowing the escape of the cerebro-spinal fluid into the wound cavity for a time, for a few days at any rate, secures a valuable new state of things, for it must get away. It does not necessarily get away through your suture opening, which remains as dry as when closed; therefore it must drain away through the lymphatics of the walls of the wound. If we can thus establish an artificial exit for the cerebro-spinal fluid by means of the lymphatics in and among the muscles surrounding the spine, then, of course, we have established a fistulous association for the carrying on of the circulation of the cerebro-spinal fluid exactly analogous to Sen's and Cushing's methods of treating hydrocephalus. Non-suturing of the theca in the operation, therefore, has a possible advantage. It is difficult to prove that this circulation exists to the degree one believes, but at any rate most of the fluid escapes in that way necessarily because it does not flow out between the stitches of the closely sutured wound. After the wound is completely healed, free mercurial inunction of the spine should be ordered, especially over the scar, on the idea that having arrested the disease an attempt should be made to secure active "absorption" and a complete restoration to health.

In concluding this sketch of an imperfectly understood chronic condition I would express the view that probably many cases of so-called acute myelitis are really meningeal in origin, and that a laminectomy and free drainage of the subdural space might arrest the whole process and the subsequent fatal injury which the cord sustains in such conditions.

As a matter of fact the circulation of cerebro-spinal fluid is so active that probably any drug introduced into the theca is very soon washed out into the wound and lymphatics.

THE sanitary staff in Cuba has recently been increased with the view of mastering the yellow fever, which has not been under complete control, and the addition has proved a fortunate step, for last October was a particularly wet month. The rain in Havana was continuous, rendering the mosquito campaign most difficult. It is, moreover, in October that *Stegomyia* is most abundant. The magnitude of the task may be judged from the fact that the number of houses visited and "petiolized" during the month was 51,381, and that there were 176 cases in which *Stegomyia* larvae were found. There were 15 cases of yellow fever in July, but these dropped to 2 in August and 1 in September, while in October no cases occurred. The work of the staff is, however, by no means confined to the war against mosquito larvae. The dairies are kept under very strict inspection, and during the month of October alone 2,416 analyses of milk were made, and only 38 samples were found to be unsatisfactory.

REPORT CXII.

OBSERVATIONS ON THE PHYSIOLOGY OF THE FEMALE GENITAL ORGANS.*

BY

W. BLAIR BELL, and PANTLAND HICK,

M.D., B.S. LOND.,

M.B., R.S. LOND.,

ASSISTANT GYNAECOLOGICAL SURGEON, ROYAL INFIRMARY, LIVERPOOL.

MEDICAL REGISTRAR, ROYAL INFIRMARY, LIVERPOOL.

I.—GENERAL CALCIUM METABOLISM.†

SINCE much of our work upon the physiology of the female genital organs has centred around the connexion existing between the calcium metabolism and the functions of these organs, it has been necessary for us to leave the bypath of our special investigation for the main road of general physiology, in order that we might, if possible, learn more than is usually known or understood concerning the rapid tissue changes which undoubtedly occur in the general calcium metabolism. We felt that unless we had some guide as to the ordinary (non-genital) influences at work we should be unable rightly to interpret or to assign proper importance to any observations we might make in connexion with the special functions under investigation.

We feel, at the same time, that it is expected of clinicians, when they leave their sphere of greatest activity, that they shall duly acknowledge and recognize the invidiousness of their position. We do this most assuredly, and most earnestly crave indulgence for the incompleteness and sketchiness of our work. In extenuation, it will be easily understood in the first place that we have been unable to devote continuous time to the work, which, consequently, has been carried on under difficulties; and, in the second place, that we have only endeavoured to get some insight into the general calcium metabolism in order to control our special observations. The real work on these general questions has yet to be done by others. We trust that some enterprising physiologists, to whom the work really belongs, will take it up—if, indeed, many of the matters to which we shall allude are not already under consideration.

In any investigation of the rôle of any product of, or factor in, metabolism, it is necessary first of all to be able to isolate that body from the tissues to which its activities are chiefly confined, and to be able to estimate any changes it may undergo quantitatively and qualitatively in different circumstances.

In order to be able to investigate the variations in the blood-calcium content, one of us (W. B. B.) devised a method for the quantitative estimation of the calcium salts. A preliminary communication was made in the *BRITISH MEDICAL JOURNAL*, April 20th, 1907, concerning this method and the reasons for which it was devised. Briefly, it consists in precipitating the calcium in the blood in the form of crystals of calcium oxalate, and, after certain dilutions and precautions against the formation of other crystals, counting those of calcium oxalate, which are very uniform in size, on a haemocytometer plate. Any slight inequality in size is corrected by the large

* The authors have been greatly indebted to the Science Committee of the British Medical Association for money grants. They also wish to express their indebtedness for assistance to Mr. George Barker, Mr. T. Williamson, and Mr. James Smith; also to Professors Benjamin Moore, Selwyn Moore, and Sherrington for laboratory facilities.

† This article is based on a paper read by W. Blair Bell, upon Some Observations on the Physiological Importance of the Calcium Salts, before the Liverpool Medical Institution, February 15th, 1908, and published in the *Liverpool Medico-Chirurgical Journal*, July, 1908.

number counted. An average of 1 crystal per square gives an index of 1 (see Fig. 1).

Since that date the method has been investigated by other observers—many of whom have been kind enough to communicate their views and results to the author of it—and the expression of opinion has been very favourable as regards its accuracy. In this respect the author has been greatly indebted to Professor Herbert Jackson, of King's College, for the deep and friendly interest he has taken in the matter, and for the comprehensive investigations made in his laboratory into the reliability of the method. His verdict is that it is an excellent clinical method.* We are ready to admit (in the present state of chemical knowledge) that this may not be a strictly accurate chemical method, for probably only the ionized calcium is precipitated and estimated; but this is of small importance so long as the method is, as we believe it to be, relatively accurate. At the same time we would point out to those chemists who have criticized the method on theoretical grounds that really they have no *locus standi* until they can define and demonstrate what amount of calcium is ionized in the blood and what is not.† We may here state that the only adverse criticisms that have come to our knowledge through the medical press or otherwise have been advanced by men who have never seen the method practised! It will, however, be observed that we are meeting criticisms that have arisen or may arise, even though they may not be worth serious consideration.¹

In further reference to the method—in augmentation or qualification of the original preliminary communication—we would like to say that we have quite recognized, as, indeed, was originally indicated, that no comparison can rightly be made between a watery solution and an albuminous solution, such as blood. In fact, strictly speaking, an index should be established for every fluid for itself. We hope eventually to indicate how this may best be done so as to bring all more or less into line, for we have always recognized that albuminous or colloidal solutions are the best adapted to this method of calcium estimation. Any actual estimation mentioned in these papers will only concern blood, unless it is specifically stated to the contrary. We have taken the normal maximum in human blood to be about 1 crystal per haemocytometer square. This is an index of 1, and is based on many observations. Whether it is strictly accurate or not is of little importance at the moment, for we have only required a relative measure.

From many communications received, and from observing the work of others not conversant with the method, we think that the main difficulties have arisen:

1. In bad technique with regard to the cleanliness of the flasks, pipettes, and plates, all of which must be scrupulously dry and clean when used.
2. In the illumination and magnification. As mentioned in the original paper, only a *dull artificial light* is of any use. An $\frac{1}{2}$ in. objective with a No. 2 eyepiece ($\times 420$ approximately) and an Abbe condenser give the best view. We cannot overrate the importance of getting the picture correctly, otherwise it is impossible to recognize the crystals for certain.

There is one more point also alluded to in the original

paper. If there is a very large number of crystals with much unevenness in size, greater dilution must be made in the initial stage of the process, and allowed for in the final calculation. Conversely, we may add, if there are exceedingly few or no crystals (very rare) to be seen, the final dilution should be lessened—say, 250 c.mm. of water should be used instead of 500 c.mm.—and allowed for in the final calculation. It has been stated that in the dilutions used calcium oxalate is soluble; we can only say that if the method is properly carried out the solubility point of calcium oxalate is never reached.

Before describing the results of the observations made we should like to discuss what value can be attributed to an estimation of the lime salts in a blood examination. In the first place, we must state that we take it as an accepted fact that the other soluble salts are concerned in the part played by the calcium salts. Secondly, we would point out that in dealing with the blood one is dealing at all times with a very variable tissue; any chemical body it contains is like an elusive Will-o'-the-wisp, which leads us a merry dance before we can come to any conclusions at all. But, after all, how can we expect otherwise? If any one ever seriously anticipated that the calcium content of the blood could be finally and definitely expressed as being one in so many thousand, as is stated in the textbooks, he must, indeed, be indicted with laboratory vision of the worst type. These things cannot be settled by *in vitro* examination. Life, as we call it, with its never-ending changes, is a necessary adjunct to metabolism.

This statement, if carefully considered, should be sufficient answer to those who have written of the "curious use"² one of us (W. B. B.) has made of the word "index" in connexion with the calcium content. This word has passed into current medical use in connexion with many other varying metabolic factors; why not also in connexion with calcium? Far better had chemists qualify the statement to be found in textbooks that the blood contains so much calcium, estimated as CaO! It may do so in regard to the special sample that was under investigation; but there the accuracy begins and ends. The use of the

word "index" makes the matter clear in regard to the method under discussion; no other word would do so.

The calcium content of the blood is, then, like that of any other food supply, a variable quantity. Apparently it corresponds to some extent with the coagulation-time variations which have been worked out by Coleman³ and others. We would emphasize the fact very strongly, however—for it seems in danger of being overlooked—that the coagulation of blood depends on many factors, of which calcium is only one, and that acting within limits. We think, however, from our own observations and from a private communication we have received from T. Addis, that it will be shown that variations in the calcium content do not cause changes in the coagulation time to the extent usually believed.⁴

In order to assure ourselves of the diurnal variations in the calcium content we each estimated the other's blood at frequent intervals throughout one day, during which we ate practically the same food and took the same amount of exercise and rest. The accompanying table shows the result.

It will be seen that, with the one exception, which may not have been quite accurate, our blood contents varied regularly and together. We have not followed the quest

* Cf. action of "Antileukozystserum" *in vitro* and in the circulation; it is diametrically opposite (Delezenne, *zt. nach. Jahresber. f. Tierchemie*, 1900, S. 141).

† Since this paper was written, T. Addis's paper has appeared. see previous footnote.

Fig. 1.— $\times 420$. Normal blood, calcium content.

* Since this paper was written, a very careful experimental criticism has also appeared. See "The Effect of the Administration of Calcium Salts and of Citric Acid on the Calcium Content and Coagulation Time of the Blood," T. Addis, *Quarterly Journal of Medicine*, January, 1909.

† In connexion with this question of "ionized" and the so-called "masked" calcium in the blood, we would point out that chemists are not all agreed. Many assert that the "masked" calcium—that is, the calcium in combination with proteins—cannot be split off and precipitated by oxalic acid. Others (see W. A. Osborne, *Journal of Physiology*, vol. xxvii, p. 400) think that oxalic acid precipitates all the calcium present.

* Error in technique spoilt this count; as far as could be seen index was about 1.0.

through the night. That is a small matter of research we leave open to others—not that we would shrink the task if we thought any knowledge of use to us could be gained by performing it.

This observation, which has been confirmed by other counts, was very instructive, and useful in helping one to form conclusions as to the value of indices under varying conditions, and showed the importance of taking the blood at the same time each day when making observations on a case, or performing experiments on animals. This diurnal variation gives confirmation also to the statement we have made that the blood is the agent of the tissues in respect of the calcium salts; and an index of the blood can, therefore, be construed into an index of the condition of the tissues.

In normal physiological conditions, if the tissues are needing calcium, one would expect to find a low calcium index—that is to say, the tissues will be taking up all the calcium they can get. There are, however, other sides to the question; for example, the calcium supply in the food may be low, or the absorptive functions in the bowel deficient; the tissues may want calcium, and the blood be unable to supply it in the form required; or, again, calcium may find its way into the blood in a reversed direction—from breaking down tissues—as sometimes occurs in pregnancy.

We refrain from mentioning further possibilities, for such a picture appears anything but easy of interpretation. It was, moreover, the complexity of these conditions which impelled us to seek out the regulating or controlling factors in the calcium metabolism, for we felt that upon some elucidation of this difficult problem depended the correct interpretation of many blood indices, and the probable deductions to be made eventually in questions of genital activity.

Let us state at once that much remains to be done in this direction, and one of us (P. H.) hopes in the near future to follow up the full relationship of the ductless glands to the general calcium metabolism, both in its normal and pathological aspects.

That the lime salts play a very prominent part in the metabolic processes of all living tissues there can be no doubt, and it is therefore somewhat strange that until recently so little interest has been displayed in the matter. The part played in bone formation, and in the coagulation of blood and milk (comparatively recent discoveries), and the so-called "tonic" influence on cardiac muscle, founded on the splendid work of Sidney Ringer, have been the only matters to attract attention, and even these have never been followed out properly.

Lately, however, a calcium "wave" seems to have come over medical science, and admirable work has been done in different departments by Sir A. E. Wright, Sir James Barr, MacCallum, and many others: even at the present time, however, the conclusions arrived at are very imperfect, and this we venture to think is largely due to the absence of a broad and comprehensive view of the subject, which alone can correlate all the issues.

We have, therefore, kept ever before us the importance of taking a wide outlook on all the work that has been done, and have attempted to harmonize our own observations of a general nature with those of the special functions we set out to study, for those functions are not local in origin or effect, but general.

Broadly speaking, then, we have come to the conclusion that the lime salts are not only necessary for the construction of the body and its growth, but also for keeping it healthy and in repair, and for the reproduction of the species.

These salts only become apparently pathological—as far as we can discover—when, like that beneficent process known as inflammation, they endeavour to rescue diseased structures and to repair them. As long as the disease—arthritis, for example—continues, so long will the reparative attempts, which include a determination of calcium salts to the part, be carried on. This reparative function of the calcium salts naturally follows on the original constructive rôle. You can cause no definite lesion, medical or surgical, in an animal, nor find one in the human subject, without there being a determination of calcium salts to the injured region, as indicated, if the lesion is severe enough, by a fall of the calcium salts in the blood until convalescence sets in—that is to say, until the demand has been met or the regulators of the calcium metabolism have established an equilibrium in the altered circumstances.

This selective and retentive power of the cell for calcium salts is probably in part under the influence of the calcium-regulating factors to be discussed presently. At the same time there is every reason to believe that individual cells exhibit a self-regulating selective and retentive power in regard to all chemical compounds with which they are brought into contact.

Had we not been able to make these observations experimentally the fact has always been there for the observing. Who has not seen the calcareous deposits at the site of many an old chronically inflamed area? It is an everyday observation in the case of tuberculous disease, but has the full significance ever been realized?

We believe that there is no such thing as calcareous degeneration. What does happen is that there is a calcification—the result of a reparative process—in diseased structures.* We would refer, in this connexion, to an extremely interesting paper by O. T. Williams, in which he claimed that the calcium soaps, which he demonstrated to be deposited in diseased appendices, were the cause of the condition known as appendicitis. Is it not possible, however, that these calcium compounds are there as the result rather than the cause of the inflammation? We would also point out that ordinary fibrous tissue, especially scar tissue, is relatively exceedingly rich in calcium salts, for the benefit of those who are at all sceptical of the deductions drawn concerning the deposition of calcium compounds.

These views, as already stated, have been entirely supported by hundreds of blood examinations, particulars of which would be superfluous here; and these observations, like those on the diurnal variations, have been of great importance in assisting us to understand the blood index.

In addition to constructive and reparative processes in which the calcium salts are retained or fixed, there are other processes no less important—indeed, it was the mystery surrounding them that led us to look for the regulating factors in the calcium economy.

Even while circulating in the blood the calcium salts play a large part in the health of the individual. We say "even while circulating," whereas, of course, we mean to speak of them in the same way as one does of the oxygen in the form of oxyhaemoglobin, or of the opsonins in the blood—in the potentialities each possesses.

It is to the metabolism associated with the rapid tissue changes rather than that associated with the retention of lime salts, already alluded to, that we now wish to call attention. Suppose that the individual is structurally and physiologically perfect for the time being, what are the processes in which the calcium salts take part? We do not pretend to know all, nor perhaps even the larger number, but we will mention briefly those which we think are most worthy of attention, and of which we have some knowledge.

In regard to these rapid tissue changes, in the first place there can be no doubt, we think, that the lime salts are largely concerned in the contraction of the involuntary muscle throughout the whole body. If we were able to abstract the lime salts from the blood, or prevent them gaining

* The deposition of calcium soaps is an intermediate stage leading to calcification.

admittance, the heart would fail and involuntary movement generally would cease. Sidney Ringer's brilliant work in this direction established these facts. In a later paper, when dealing with uterine contractions, we shall illustrate the effect of calcium salts upon the heart. We do not for one moment say that involuntary muscles cannot be affected by other chemical and physical agents, but there is very strong evidence to show that the calcium salts play a large part in the production of the normal stimulus, and—to speculate—probably of the primary stimulus in the embryo. In subsequent papers we shall deal with the question of uterine contractions, and also with the processes with which calcium salts are concerned in menstruation, pregnancy, and lactation.

We have made, also, some observations in regard to the calcium content of the blood and its coagulability, and while we have not made any serious study of the question—for T. Addis, of Edinburgh, has informed one of us in a private communication that he has this matter in hand—we would like to make a few remarks upon the subject here.

We have often been asked if there is not a certain element of danger in the free administration of calcium salts. From many observations and experiments we feel quite justified in saying No. One cannot force up the calcium index in the blood much beyond the usual maximum, in normal circumstances, either by oral administration or subcutaneous injection, and even if this were possible—to have a lawyer's alternative—clotting in the vessels, if they were healthy, would not occur. We have killed animals with intravenous injections of calcium salts without producing intravascular clotting, *except where the vessels had been previously damaged*. There is therefore, we think, an optimum amount with a quickest normal clotting time, and the latter excess of calcium salts cannot increase. Given, of course, an inflamed or damaged vessel—for example, phlebitis after typhoid fever or arteritis—and one may get a deposit of lime salts in the damaged walls (vide supra), and possibly clotting in the damaged vessel, which will be most likely to occur if the calcium optimum index for clotting exists.

One more point in this connexion. Sir A. E. Wright showed that the oral administration of an excess of calcium—which we presume he thought got into the blood—delayed clotting; but apparently, from observations we have made, this is not due, as he thought, to an excess, but to a deficiency, in the blood. It is probable that after excessive dosage the body becomes immune or resistant to the absorption of calcium salts, or excessively active in their excretion, effected probably by the thyroid secretion. This point might with advantage be studied in infant feeding and rickets.

Of the many other points that have interested us in taking a general survey of the calcium metabolism we may single out two which have brought into our minds matters of some importance.

If we are right in our main belief that the calcium metabolism is largely concerned in the physiological processes of women, may not the alteration in the calcium economy at the menopause be to some extent accountable for the deposition of fat? This does not of course coincide with the general ideas concerning obesity and the allied metabolic processes to which that condition is usually attributed; but in view of the close connexion between certain fatty acids and calcium metabolism we feel that there may be some association which future investigation will lay bare. Excellent work on the relationship of these fatty acids to one another in regard to the absorption and deposition of fats, and on the formation of calcium soaps has already been carried out by O. T. Williams (loc. cit.).

The other suggestion we would make is this: May not the deficient excretion of calcium soaps by the bowel in physiologically active women be the cause of chronic constipation—an ever-present evil with the female sex? We think these points are well worthy of bio-chemical investigation.

Before discussing the regulating factors it may be well to include here an observation which has given rise to some controversy. While looking for a suitable organic compound of calcium for hypodermic injection it occurred to us to try gelatine, which, as is well known, contains a large amount of calcium; indeed, it has been suggested

that the power of gelatine, when used therapeutically in cases of aneurysm to influence the coagulability of blood, is due to the contained calcium.*

We were consequently led to investigate this animal product, and found that by the method already described it was possible to estimate the calcium. Though, of course, not strictly comparable with blood, we may state that, although the commercial samples vary, we found the average index to be about 20. It will be readily understood how this quantity might influence the blood of the individual into whom it was injected. As yet no direct experiments have been done in this direction, but we found that intravenous injection of 4 per cent. gelatine solution did not cause intravascular clotting. Gelatine corresponds, therefore, with other calcium compounds in this respect, and by this behaviour tends to confirm the suggestions that its calcium content is responsible for the raised coagulability, if this does occur, rather than any nucleo-proteid-like substance.

The following protocol illustrates the action of a 2 per cent. solution of gelatine subcutaneously injected upon the systemic blood calcium content.

White Buck Rabbit.			
November 1st, 1907:			
9.45 a.m.	Index 0.67	10 c.c.m. 2 per cent. gelatine solution injected.	per cent. gelatine subcutaneously
11.45 a.m.	" 0.67		
12.45 p.m.	" 0.7		
3.45 p.m.	" 0.7		
5.40 p.m.	—	10 c.c.m. 2 per cent. gelatine solution injected.	subcutaneously
5.55 p.m.	Index 0.76		

If, therefore, the gelatine does raise the calcium content of the blood a 2 per cent. solution does not appear to be strong enough. It is only fair to state that Boggs⁸ found the period of increased coagulability to be at a maximum as long as twelve hours after the injection. The diverse results obtained in the experiments of Boggs and the conflicting opinions of Dastre and Floresco⁶ on the one hand, and those of Brat⁷ and Sackur⁹ on the other, regarding the influence of gelatine upon the coagulability of the blood may be explained on the theory of immunization we have already alluded to, or—and this is more likely—on the ground that the methods employed by them for estimating the coagulability were inaccurate.

It was in connexion with the coagulation, or "setting," of gelatine that we made some observations which have given rise to controversy. The results of our experiments led us to ask if it was not possible that the presence of calcium was necessary for the occurrence of this process. In October and November, 1907, we carried out a series of experiments in which we tried the effect upon the coagulation of gelatine of solutions of the following substances: oxalic acid, acetic acid, ammonium oxalate and sodium citrate.† We do not think it necessary to give the protocols in detail, but will briefly summarize our results.

We found that we obtained a heavy white precipitate of calcium oxalate with ammonium oxalate and oxalic acid, and that the salts above mentioned caused marked retardation of the coagulation time. Further, that the acids (if the gelatine was in weak solution) also retarded the coagulation under ordinary circumstances; but that if the solutions were kept at a temperature which would prevent gelatinization for about forty-eight hours, that process did not occur at all. Further, we found that the prolonged action of ammonium oxalate, but not of other salts, prevented coagulation.

Now, in regard to the criticisms raised with reference to the suggestion that it might be worth while for chemists to discover if calcium was really an integral part of gelatine, and whether gelatine existed as such without calcium—in the first place, let us state that in all the papers quoted to disprove our suggestion (it has never been more than a suggestion) there is no mention of calcium-free gelatine having been obtained. Morner¹⁰ and

* See previous note.

† Compare these experiments with the statements made by H. E. Roaf (Reference¹¹).

many others have done their best to obtain calcium-free gelatine, but as far as we know no one has succeeded. It seems to us, therefore, that, whether our suggestion is right or wrong, it is hardly logical to argue that because a certain percentage has been removed without interfering with the coagulability, calcium has therefore nothing to do with the process. In regard to this point, Addison's work on blood coagulation is of much interest.

Nor does it appear reasonable to assume, as has been done,¹ that because in certain experiments delayed coagulation only was obtained, therefore the calcium cannot be concerned. We have secured prevention of coagulation, but to that we do not wish to attach undue importance, although such positive evidence is certainly of more value than the negative evidence just alluded to.

It has also been suggested that the hydrogen ions in the oxalic acid are responsible for the result. This seems to be quite as indefinite a statement, and one which requires some proof. However, until calcium-free gelatine has been obtained which will gelatinize, and so prove our suggestion to be wrong, we would commend to unbiased observers the following points which seem to us to be worth consideration in any attempt to settle the question:

If calcium is a factor in the coagulation of blood—and we believe that this is usually accepted—and oxalic acid and ammonium oxalate prevent that coagulation by precipitating the calcium, is it not possible that the same result obtained in the case of gelatine is due to the same cause? Again, most salts retard the coagulation of blood, just as the "setting" of gelatine is delayed by them. C. J. Martin¹⁰ attributes the result obtained by citric acid and citrates in the case of the blood to an alteration in the ionization of calcium; and this is, we believe, universally accepted. Is it not possible to apply the same idea to the action of these and similar compounds upon gelatine? This is a small matter, perhaps, and we have no wish to discuss it at greater length, as it in no way concerns our work; but, having made a promise to deal with any criticisms raised,¹ we have therefore attempted to fulfil it.

In our investigations we have so far touched but slightly upon the importance of the ductless glands in the regulation of the calcium metabolism. Time has not allowed that complete inquiry which will, as already mentioned, be pursued later by one of us. There are several points, however, to which we desire to draw attention, for they seem to have some relation to genital activity.

First, in regard to the thyroid gland. Clinically, we had observed that in most cases of exophthalmic goitre, where the thyroid secretion was in excess, the blood calcium index was low, an observation which caused us to suggest to Sir James Barr that calcium salts might possibly have some therapeutic, or at least symptomatic, advantage in this disease. Sir James Barr very kindly gave these salts a trial, with undoubted advantage in many cases, the pulse-rate being markedly lowered.

Following this up, we excised the thyroid, and as far as possible the parathyroid glands of four cats. Two were quite young, and two full grown. Two died in a few days—one young and one adult—the former with tetanic convulsions on the fourth day, and the adult a few days later with slight spasms and great muscular weakness.

The other young cat died at the end of fourteen days, much emaciated, and with great muscular weakness. The last—a large black tom-cat—was becoming lethargic and myxoedematous, so we castrated him. From that time he steadily improved, and is at present quite lively and particularly intelligent. His coat is perhaps a trifle dull and dusty-looking, otherwise there is nothing at all indicative of myxoedema.¹¹ This effect of castration, if one can claim so much in a solitary instance, requires further investigation. We have been told that Stanley Kent obtained the same result, but never published an account of his experiments.

With regard to the observations made on the blood of these cats, in each of the young cats the calcium index ran up to a remarkable extent, while the older cats were not affected in the same way. All the animals lost weight.

The following are the protocols of these experiments:

I. Large Tortoise-shell Tom-cat.

November 25th, 1907. Index 0.78. Weight 3,350 grams. Complete thyroidectomy.

¹¹ Recently an improvement in the condition of his coat has been brought about by the administration of thyroid gland extract.

November 28th, 1907. Not well; lying very quiet. Slight muscular twitchings.

November 29th, 1907. Very quiet. Spasms when touched. Some muscular weakness. Index 0.74. Given 5 c.cm. thyrocal solution and 5 c.cm. 20 per cent. gelatine solution.

November 30th, 1907. Better. Still weak. No spasms. Index 1.3.

December 1st, 1907. Died during night. Weight 2,800 grams.

II. Young Tortoise-shell She-cat.

November 25th, 1907. Index 0.48. Weight 1,550 grams. Complete thyroidectomy.

November 28th, 1907. Very restless; quite strong.

November 29th, 1907. In continual tetanic convulsions; cannot stand. Index 5.5. 5 c.cm. thyrocal solution hypodermically and 5 c.cm. gelatine solution 20 per cent.

November 30th, 1907. Convulsions more intermittent. Still violent. Index 9.0. 10 c.cm. thyrocal solution given hypodermically.

December 1st, 1907. Better. One slight convulsion. Very weak. Index 3.0.

December 2nd, 1907. Died during the night. Weight 1,240 grams.

III. Young Black Tom-cat.

November 27th, 1907. Index 0.67. Weight 1,750 grams. Complete thyroidectomy.

November 29th, 1907. Apparently quite well.

December 1st, 1907. Index 2.7.

December 5th, 1907. Index 14.0. Cat getting weak.

December 6th, 1907. Index 15.0. Cat much weaker.

December 7th, 1907. Index 11.0. Cat still very weak, but seems a little brighter.

December 8th, 1907. Index 12.0. Cannot use hind legs. Injection of 5 c.cm. thyrocal.

December 9th, 1907. About the same condition. Weight 1,210 grams.

December 10th, 1907. Index 7.0. Cat seems much better. Injection of 5 c.cm. thyrocal.

December 11th, 1907. Index 18.0. Cat seems not nearly so well to-day.

December 12th, 1907. Died during the night.

IV. Large Black Tom-cat.

November 27th, 1907. Index 0.3. Weight 3,250 grams. Complete thyroidectomy.

November 29th, 1907. Apparently well.

December 1st, 1907. Index 0.7. Apparently well.

December 5th, 1907. Index 0.5. Very quiet.

December 6th, 1907. Index 0.4. Rather weak.

December 7th, 1907. Index 0.8. Seems better than he was yesterday.

December 8th, 1907. Index 0.4. Seems strong but very lethargic.

December 9th, 1907. Index 0.4. So dull and apathetic that he is apparently developing myxoedema. Weight 2,890 grams. Castrated.

December 10th, 1907. Index 0.3.

December 11th, 1907. Index 0.6.

December 12th, 1907. Index 1.0. Quite active and bright. Stole some fish.

December 23rd, 1907. Index 1.0. Apparently normal.

We likewise operated upon three rabbits, but in none of these did we get the results obtained with cats. Beyond some temporary loss of weight they showed hardly any symptoms at all; nor did the calcium indices show marked increases. It will be noted, however, that the only one at all ill was the young one. The primary drop in the calcium content which follows all operations occurred, and was followed by a gradual restitution to the normal. This is seen from the following protocols:

I. Grey and White Buck.

November 23rd, 1907. Index 0.8. Weight 2,700 grams.

November 24th, 1907. Complete thyroidectomy.

November 25th, 1907. Index 0.57.

November 26th, 1907. Index 0.45.

November 27th, 1907. Index 0.3.

It is, however, well known that rabbits and herbivorous animals generally do not exhibit the effects of complete thyroidectomy and parathyroidectomy (if the latter is effected, which is somewhat doubtful) to the same extent as carnivorous animals. This probably explains the results of our experiments on rabbits.

There can be little doubt, we think, that the thyroid secretion plays some part in the calcium metabolism along, perhaps, with other functions, and the evidence all seems to point to an excretory effect.

Scordo and Franchini (Crocco's Clinic)¹¹ have recently arrived at the same conclusion from a careful examination of the calcium excretion in the urine of patients suffering from exophthalmic goitre. On the other hand, MacCallum and Voegtlin,¹² in their work on the parathyroids and calcium metabolism, arrive at a different conclusion. There must be, however, some connexion between the secretion of the thyroid gland and the calcium metabolism, even if only an intermediary one, and we shall allude to this in a later paper in regard to thyroid activity during menstruation and pregnancy.

Next, the pituitary gland has engaged our attention. It is hardly necessary to say that the gland has frequently been found to be diseased in connexion with bony overgrowths, such as one finds in acromegaly; consequently it is natural to imagine that the secretion of the gland is normally concerned in the limitation of bony deposition, or calcium retention. But, further, it is found that the extract made from the infundibular portion of the gland (Fig. 2, 1)—strangely enough the non-glandular portion—has an enormously powerful influence upon involuntary muscle fibre. This effect is most marked upon the uterus, as we hope to show in a later paper. The glandular portion of the gland (Fig. 2, 2) is inactive in this respect. Mr. H. H. Dale, of the Wellcome Laboratories, who has kindly furnished us with the extract, has done much good work on this subject. Professor Schäfer, however, was the first to remove the pituitary gland from the lumber room of "embryonic relics."

We have reason to believe that further investigation will show that an intimate connexion exists between the pituitary extract and the calcium metabolism. Our experiments have been limited in number, but seem to show that under the influence of pituitary extract there is an

increase of calcium in the blood, whether it is a normal or permanent effect we are not at the present moment prepared to say.

Again, adrenal extract, as every one knows, has not only a marked influence on involuntary muscle, but also causes calcium retention in the tissues. Acting upon this knowledge, Bossi¹³ of Genoa has found that osteomalacia can be much improved by the administration of this product, and experimentally it has been shown that calcareous retention in the blood vessels is brought about by its influence.¹⁴ This, however, may be a natural process consequent upon a arteritis.

Lastly, the ovaries (and testes possibly also) influence calcium metabolism, as is shown in many ways: osteomalacia has been cured by oophorectomy, and we know that calcium retention occurs after the menopause. It is possible, also, that the part played by the internal secretion of the ovary in menstruation and pregnancy has reference to the calcium metabolism concerned in these processes.

This syndrome of facts leads one to many speculations — speculations which must be checked by careful experimentation. It seems, however, more than probable that the ductless glands preserve a balance in the calcium metabolism — as they do in many other metabolic processes — one acting anabolically, another katabolically.

It is sufficient for our present purpose to know that there is some important relationship, but we hope in the subsequent papers to indicate and illustrate more fully the connexion that exists between these glands and the functions of the female genital apparatus.

Fig. 2.—Pituitary gland ($\times 250$). Note sharp line of demarcation between hypophysis and infundibulum.

ON SLEEP AND WANT OF SLEEP.

BY

THE RIGHT HON. ROBERT FARQUHARSON, M.D.

"A blessing on him that invented sleep. It wraps us up like a garment," and "Sleep that does weigh our eyelids down, and steep our senses in forgetfulness." These hackneyed quotations sum up the case in favour of Nature's sweet restorer, and we all sympathize with the poor monarch who in vain sought the nightly refuge from the trials and worries of the world so freely granted to the meanest of his subjects.

I am not going to attempt to be instructive in this paper. My ambitions do not point so high, and I should like to imitate the man who, if not witty himself, was the cause of wit in others, by inducing more especially general practitioners of large practical experience to help in clearing up some still obscure points in connexion with sleeping;

and perhaps consultants and scientific experimentalists will have a look in too, and join a symposium to instruct more ignorant people what sleep really means, how it is lost, and how it can be regained quickly, efficiently, and safely. In the first place, is it not the case that there must be varieties of sleep? Unless the classical researches of Durham have been superseded by some industriously obtrusive German, it must be still taken as proved that the physiological process known as sleep results from an anæmic condition of the brain. But then there is a pathological variety. The stertorous coma of apoplexy, the anæsthetic unconsciousness of chloroform or opium poisoning, the nodding off after a heavy dinner or a good dose of the stronger wines, the sleep of utter exhaustion when we read of soldiers falling asleep on the march, little children tired out with the irrepresible vivacity of their waking hours, and the classical instance narrated by Sir Thomas Watson, and painted by Sir Charles Bell, of the man who had been operated on for tracheotomy.

"Though half a dozen candles are held close to his face to throw light on the wound, and though the surgeons, their hands smeared with blood, are still busy about his throat, making arrangements to ensure the patency of the orifice, the patient falls asleep."

I have known three very distinguished men who never could keep awake after dinner—Sir J. FitzJames Stephen, the late Sir George Campbell, and Lord Strathnairn. This illustrious general was excessively hospitable, and when I was quartered in Dublin, hardly a day passed without his orderly riding into barracks to invite some of us to dinner. Before the wine was placed on the table the old gentleman invariably began to nod, and when his forty winks were over he pulled himself together, sprinkled his face freely with cold water, and was bright and brisk for the rest of the evening. And some judges scandalize the court by their invariable habit of dropping into a deep sleep in the middle of a case about which they eventually have to give judgement. This would seem a convenient time to ask the question to which I have never yet succeeded in getting an answer—why these short naps of five or ten minutes, snatched in the middle of work, or even of play, are so extraordinarily refreshing? Over and over again, when completely tired out with the rush and bustle of London, or the strenuous increasing strain of parliamentary life, I have closed my eyes when I felt an "exposition of sleep" coming over me, and have waked up more pulled together than even by seven or eight hours between the sheets; and why, on the other hand, the same dose, administered in the early morning after the first waking, makes one sleepy, sluggish, and irritable, and easily worried during the rest of the day? How, again, are we to explain the irresistible onset of sleep which comes upon us when listening to a dreary sermon or lecture, or reading a dull book, or trying in vain to follow a wearisome debate in the House of Commons? So much, then, for the causes of sleep, and shall I be considered very stupid if I venture to ask what the precise physiological conditions are under these varied circumstances? Anæmia cannot explain them all, so will some one tell me in easy and simple language, devoid of scientific technicalities, and especially avoiding the jaw-breaking phrases that are worse than Greek and Hebrew to some of us, which depend on a full-blooded brain, and to which the very ingenious experiments of Durham specially apply?

Now for some of the reasons why we do not sleep. An overtaxed brain is a frequent cause. They say that the only time Gladstone went off his sleep was during his anxiety for Gordon during that anxious time at Khartoum. As a general rule, on retiring from the House after the most strenuous debates, he invariably laid down his troubles at his bedroom door, brewed himself a cup of tea, and read for an hour or so some novel recommended by his daughter, who was his censor of the press. This seems to be rather curious—the double action of tea. Undoubtedly one often feels drowsy after drinking it; and young ladies, on returning from a ball, frequently take it to soothe their nerves, whilst, on the other hand, nothing is more certain than its irritating effect in preventing sleep. Probably the warmth of the infusion explains its soporific action, for a copious draught of almost boiling water is well known to woo the gentle goddess effectually. Some people need a nightcap of whisky, hot or cold, while

others insist on a superadded pipe; and there is no doubt that weakly people are often made to sleep soundly by being furnished with some easily digested nourishment after getting into bed. Then the room must neither be too hot or too cold, the bed must be properly placed, the weight of clothing must be carefully regulated by the temperature; chilly mortals appreciate a hot bottle, and whilst some cannot sleep with an open window, others are obliged to fling it wide before slumber can be obtained.

Heavy suppers must be avoided, and champagne in particular; either keeps people wide awake, or makes them restless, and obliged to sit up or get up, and toss about on their pillow at an unusually early hour. Of course, worry must be avoided, and it is wise not to open letters at night, lest they contain something disconcerting or depressing. Any regular noise, like a crowing cock, or a barking dog, or a squalling baby, must be suppressed, and the brain must be kept at rest as far as possible, although some people are soothed by a little reading just after turning in. Music, they say, has power to soothe the savage breast; and a good story may be recalled of one of Lord Rosebery's daughters, who was taken to task by the nurse for thinking too much after she got into bed, and who replied, "You know, I can't make my mind sit down."

It is the fashion to say that you can cure insomnia by counting up to a regulated number, or imagining sheep jumping over a gap, or some device of that kind; but I have never yet met any one who would confess to having derived benefit from these domestic expedients. So at last it comes to this, that everything else has failed and we must have recourse to narcotics; and here some important ethical questions come in. Some physicians—rather pedantically, I think—will not give their sleepless patients relief by drugs for fear they get into the habit of taking them regularly. Of course, we cannot altogether ignore this view; but Sir Lauder Brunton, the wisest and most suggestive of modern physicians, once put the case in a nutshell by saying, "Insomnia is a bad habit, and may become permanent if we do not break it."

So what are the best remedies, how should we use them, and what are the contraindications and dangers attending their use?

Now, this brings us to what is or ought to be admitted as the most difficult and delicate bit of therapeutics. To begin with, idiosyncrasy, that baffling and inexplicable individual peculiarity, introduces an element of difficulty and danger. The old saying, "What is one man's meat is another man's poison," applies still more emphatically to drugs, and we may get into great trouble if we do not "gang warily" when dealing with narcotics. For instance, a single drop of laudanum has been known to kill a baby, and yet, whilst I have seen a woman display well-marked physiological symptoms after a few 10 minim doses, I have often prescribed 20 minims of the tincture of belladonna for a child of 2 years without anything of the kind; and it is well known that a single application of the liniment will bring out a very irritating papular eruption on some skins. Certain people can take large quantities of opium without bad effects, and toleration is rapidly produced. James Payn graphically describes how he saw De Quincey toss off the best part of a glass of laudanum without the slightest inconvenience.

Then take my own case. Bromide of potassium, which so effectively soothes the nervous system and causes refreshing sleep as a general rule, even when pushed to heroic doses, has never had the slightest effect on me, and the same remark applies to the entire synthetic series, with the single exception of veronal, which cannot be used freely without unpleasant and even dangerous effects. Now, to choose our special form of drug. After all, nothing equals the rapid and eminently soothing sleep given by morphine, and its subcutaneous use not only relieves pain as by magic, but beats any other form of tonic and stimulant clean out of the field. Chloral depresses the heart, and must be used with caution, for the uncertainty of its action warns us to feel our way with great care in prescribing it, for death has been known to follow a single dose of 30 grains, and a series of cases has been recorded in which symptoms arose akin to blood poisoning, with purpuric and scorbutic eruptions, ulceration of the gums, and great prostration, ending in death; and I have known a single

moderate dose of bromide of potassium bring out the unsightly and irritating, eruption of acne which is one of its most unpleasant physiological effects. The great advantage of sulphonal is that it may be continued for prolonged periods without increasing the dose. The late Sir Henry Thompson at one time took a nightly draught, which had to be very carefully prepared because of its insoluble nature; and an active and energetic friend of mine, and one of the best shots in Aberdeenshire, has taken 10 grains three times a week for many years with good effect, and has never found it necessary to go beyond that quantity; on the other hand, it is not quite free from danger, and not very long ago an elderly lady friend of mine died from evident accumulation in her system from a series of not very heavy doses taken for purely narcotic purposes.

So much for the choice of narcotics; may I say a few words about the anatomical or pathological conditions which may interfere with their action? Sleep being produced by anaemia of the brain, what is the effect of the rigidity of the arterial system in advancing years, and which, of course, prevents the rapid variation of the conditions of circulation within the cerebral mass? and what is the precise effect of pregnancy, or alcoholism, or diabetes, or glycosuria, or Bright's disease, or blood and urine loaded with uric acid, or a congested liver, or blocking of what old-fashioned writers used to call the "primae viae" by chronic constipation? Space forbids me to pursue this suggestive line further, but if the Collective Investigation Committee of the British Medical Association, which formerly did excellent work, still exists, I would recommend this subject to their earnest consideration. For, so far as I know, either there is no sufficient information to guide us or it is so scattered as to be of comparatively little use; and further contributions to our knowledge will be gratefully received and acknowledged by those who, like myself, are ignorant, perhaps through no fault of our own.

The Morison Lectures

ON THE

PATHOLOGY OF SYPHILIS OF THE NERVOUS SYSTEM IN THE LIGHT OF MODERN RESEARCH.

DELIVERED AT THE ROYAL COLLEGE OF PHYSICIANS,
EDINBURGH, JAN. 25TH, 27TH, AND 29TH, 1909.

By F. W. MOTT, M.D., F.R.S., F.R.C.P.,

DIRECTOR OF THE PATHOLOGICAL LABORATORY, LONDON COUNTY
ASYLUMS; PHYSICIAN TO CHARING CROSS HOSPITAL.

LECTURE III.

I ENDEAVOURED in my last lectures to indicate some of the advances made in our knowledge of the biology and bio-chemistry of syphilis, and in this my last lecture I will try to correlate the facts with clinico-anatomical knowledge, especially in relation to the etiology of the parasyphilitic affections, tabes, and general paralysis.

PARASYPHILIS (FOURNIER); METASYPHILIS (MOEBIUS).

Parasyphilis is the term given by Fournier to those diseases of which syphilis is essentially the cause, but which are not directly the result of the syphilitic virus. Such diseases are: General paralysis, tabes dorsalis, tabo-paralysis, and primary optic atrophy. These diseases are really a single morbid entity owning the same cause; insidious in onset, progressive in character, and uninfluenced by antisiphilitic remedies. These various clinical types of parasyphilitic disease are the result of a primary neuronic dystrophy; they have a similar pathogenesis, and may occur simultaneously or successively in the same individual. In tabes dorsalis the spinal sensory protoneurons are affected; in general paralysis the cortical association neurons; in tabo-paralysis both are affected simultaneously or successively. The dystrophic process is due to a lack of durability of the neurons; it may be a slow process of decay and death of the intraspinal portion

of the sensory protoneurons, as in the case of tabes dorsalis; it may be a rapid process of decay and death of systems and communities of neurons of the brain, as in general paralysis. The former is a smouldering destruction of neural elements, the latter a conflagration often fanned into flames by microbial toxæmia, autotoxæmia, or circulatory disturbances associated with arterial anaemia and venous congestion with blood stasis of the brain. It is probable that Erb's spinal paralysis and certain cases of amyotrophic lateral sclerosis may be primary post-syphilitic dystrophies.

Fournier thus classifies parasyphilitic affections:

I. ACQUIRED SYPHILIS.

1. Acute hystero-neurasthenia of the secondary period.
2. Different neurasthenic manifestations of a more advanced stage.
3. Tabes.
4. General paralysis.
5. A special form of epilepsy.
6. A special form of muscular atrophy.

II. HEREDO-SYPHILIS.

Numerous dystrophic troubles, general or partial; malformation, notably dental; arrest or retardation of physical and intellectual development, infantilism, dwarfism, inborn lack of vitality, cachexia, marasmus, rickets, hydrocephalus, certain forms of simple meningitis in early life, possibly certain cases of true epilepsy, juvenile tabes, spinal and optic juvenile general paresis. The gravity of these affections lies in the fact that they are uninfluenced by antisiphilitic treatment. The local and general failure of development may be due (1) to the direct influence of the virus upon the life and growth of the tissues, or (2) indirectly to exhaustion of the specific energy of the cells of the central nervous system by the establishment of an altered metabolism, the bio-chemical nature of which is not yet fully understood. But, as a provisional hypothesis, we might suggest that the unloosening of lipid substances into the blood, which we know occurs in congenital syphilis, may lead to a defective *vita propria* of all the cells of the body. In some lesions of congenital syphilis it may be actually due to the local invasions and multiplication of the spirochaete, for they have been found in abundance in situations where local lesions exist—for example, the epiphysis of bone—and why not in the epiblastic enamel germs?

We might provisionally suggest as a hypothesis that in all cases of acquired and congenital syphilis the living contagium, spirochaete, excites the tissues and fluids of the body to a defensive reaction. The difference in the effects of inoculation may depend upon the virus itself. Some striking examples will be given later on which apparently indicate that there may be a special neurotoxic virus, and if such instances were more numerous we could hardly believe that coincidence could explain the facts. If, as there is reason to believe, the *Spirochaeta pallida* is the living contagium, and that, becoming generalized in the lymph and blood stream, it produces the secondary manifestations, then there is a certain amount of chance what tissues will be attacked; for the living agent, swept along in the blood stream, may become lodged anywhere, and, by blocking capillaries, cause a local focus of tissue infection. The existence of a generalized eruption implies virulence of the circulating blood, and experiments demonstrate the fact that the blood is virulent during the eruptive stage; thus, Neisser has obtained a positive result by injection of blood into the skin in the chimpanzee, and Roux and Metchnikoff have successfully inoculated a macaque monkey from the blood of the chimpanzee in the eruptive period. It would be of great interest to know how long the virulence of the blood persists after the generalized eruption, or if the consecutive attacks which may occur even after fifteen or twenty years are explained by the "contagium vivum" remaining latent in the lymphatic glands or some deep-seated organ. What is the evidence in favour of this view?

It is generally admitted that the subjects of tabes and general paralysis are recruited especially from those individuals who have had a mild attack and who very seldom show any signs or symptoms of tertiary gummatous skin, visceral or bone lesions. Fournier states: "The comparative mildness of the primary constitutional symptoms in those who ultimately

mately become tabetic would almost seem to indicate that, when the syphilitic virus expends itself in severe primary and secondary manifestations, there is a less tendency to the subtle poison which proves so disastrous to the nervous system." From an experience of over 500 necropsies made on paralytic patients I have been surprised at the rarity of severe tertiary skin and visceral lesions as compared with the cases of true syphilitic brain disease. Arterio-sclerosis, in the form of fibrotic plaques of the aorta, is, however, very common in paralytic dementia, which, however, is now regarded as a parasymphilitic affection. Again, although paralyses in the prodromal stages of the disease often give themselves up to debauchery and sexual congress with loose women, I have never seen or had my attention called to a case of general paralysis among the vast numbers in the London County Asylums that showed a primary sore or a secondary rash. Krafft-Ebing noted the same fact, and concluded that the reason was that every paralytic had had syphilis and was therefore immune. He caused this hypothesis to be put to a crucial test. Nine cases of general paralysis were selected that gave no history and showed no signs on the body; these patients were inoculated with the virus of a typical hard chancre and watched for 180 days. They presented no signs of infection. The only assumption is that they were immune owing to previous infection, and that they possessed a power of resisting the action of the syphilitic virus. The concordance of this result with the statistical data of antecedent, inherited, or acquired syphilis in cases of tabes and general paralysis given later, led to the widespread acceptance by neurologists of the view that tabes spinalis or cerebri (general paralysis) is essentially of syphilitic origin. No syphilis, no tabes. Only a few eminent neurologists, such as von Leyden, refuse to accept the syphilitic origin of tabes, and one of the arguments employed against this view is that antisymphilitic remedies are of no avail in preventing the disease or arresting its progress. Moreover, we know that many people develop general paralysis or tabes dorsalis, even though they have been treated with mercury systematically from the primary infection onwards. So much has this impressed some authorities that they have even asserted that overmercurialization is the cause of the disease in question. The average time which elapses between the primary sore and the onset of tabes and general paralysis is, according to the observations of Schuster, the same in persons who have been thoroughly treated with mercury and those who have either not been treated at all, or only insufficiently. All the facts, therefore, go to prove that the syphilitic virus has in some way or other damaged the durability of the neurones, so that systems or communities die prematurely. It has been observed that Fournier includes other functional and organic diseases of the nervous system among the parasymphilitic affections. We have less knowledge concerning them and their pathogenesis. I have, however, seen cases of general paralysis in which the motor symptoms were most pronounced and the dementia slight, in which all the deep reflexes were exaggerated, and the plantar extensor reflex present on both sides—a very unusual occurrence in the ordinary paralytic dementia. At the autopsies there was a well-marked sclerosis of the crossed pyramidal tracts without any coarse lesion in the brain and cord to account for it. I have also seen cases of progressive amyotrophic lateral sclerosis occurring in the subjects of syphilis which appeared to be the result of the progressive degeneration of the whole motor efferent tract from cortex to periphery without any sensory disturbance. Some of the cases of Raymond cited by Fournier (*les affections parasymphilitiques*) with sensory troubles, namely, rheumatic pains and paraesthesiae, are obviously, from the account given of the appearances of the spinal cord *post mortem*, cases of subacute gummatous meningitis involving the roots. The serum diagnosis and the examination of the cerebro-spinal fluid bio-chemically and microscopically will permit us in future to determine whether syphilis is the essential cause of these degenerations. For every nervous disease, whether functional or organic, occurring in a person who has suffered from syphilis is not necessarily syphilitic in origin, yet when we consider the profound influence the virus has upon the blood and tissues of the whole body, it is not illogical to assume that any disease, local or constitutional, functional or organic, occurring

in a person who has acquired or inherited syphilis may possibly have found a suitable soil for development, owing to the diminished vital resistance of the tissues occasioned by such a potent and persistent poison as syphilis. Thus syphilis, although not a direct agent in such a case, by its devitalizing influence and the impoverishment of the lipoids, becomes an important indirect causal factor of the disease in question. There are many known ways in which syphilis can cause functional disturbances of the nervous system and lead to the development of neuroses and psychoses. The theory of the possibility of the syphilitic virus, or the lipid products of its activity, stimulating the neurones to increased dissimilative action and exhaustion, has been shown to have considerable support from recent investigations. There are, however, other conditions which are well known—namely, the change in the blood and blood vessels, and in the lymph and lymph channels. Long ago Virchow pointed out that in syphilis there is a diminution of red blood corpuscles and a hyperalbuminosis. Later, Schülgowski, Hafter, and Laacke described a considerable fall in the red blood corpuscle count. In the secondary stage Martin and Hiller, also Letzius, showed that not only is there a diminution in the number of red blood corpuscles, but also an absolute diminution of the haemoglobin content of the corpuscle. Anz found, besides the fall in number of the red blood corpuscles, an increase of the white, so that one can speak of a relative and absolute leucocytosis. Later observers showed that there was a diminution of polynuclear leucocytes, and that the leucocytosis was due to a great increase of lymphocytes, which increase we may associate with the polyadenitis. Further, there is an increase of eosinophiles. These changes in the blood in the secondary period increase in intensity with each fresh series of syphilitic manifestations, and diminish as they diminish; moreover, the blood changes disappear with the disappearance of the secondary symptoms under antisymphilitic treatment. Fournier long ago described the favourable influence of mercury upon the blood formation; clearly, then, the mercury, by its influence upon the productiveness of the syphilitic virus, allows a return of the normal haemopoietic formation, or arrests a too rapid haemolytic action. The French authorities were the first to call attention to a syphilitic anaemia, and to point out that iron had no influence thereon. The ebb and flow of the amount of oxyhaemoglobin is correlative to the flow and ebb of lymphocytes, which might indicate that, with the pouring out of an abundance of lymphocytes from the lymph stream into the blood stream, there was associated a pouring out of the virus that occasioned the irritation and hyperplasia of the lymph-cell elements. Hoffmann asserts that he has observed the serum of a syphilitic patient produce immobility and agglutination of the spirochaetes. Perchance it is that when the virus can no longer be neutralized by the defensive reaction of the blood serum embolic capillary effects are produced, causing papular eruptions of the skin, mucous tubercles, and occasionally meningitis. Selenow demonstrated blood changes before the outbreak of the secondary exanthem, therefore before the secondary incubation stage. It is probable that before the eruption becomes visible, microscopic changes have occurred in the affected cutaneous capillaries and adjacent skin structures, much in the same way as in the primary sore; consequently, we should expect a blood change to precede the eruption. The anaemia may be due to a haemolysis owing to an unloosening of lipid substances (lecithins and cholesterol) from the red corpuscles by the action of a toxic substance of the virus acting as a lipolytic ferment disintegrating the osmotic membranes or by chemical interaction in the lecithin and cholesterol complex, forming the osmotic membrane producing physical changes by which the membrane becomes permeable even to the large haemoglobin molecules (Fig. 12). It may be supposed that the protein stroma of the corpuscle is covered by a film or membrane formed of this lipid substance, and the virus acts upon it in such a way as to dissolve, dissociate, or destroy the membranous film covering the corpuscle, and causing thereby a liberation of both the haemoglobin and the lipid substance into the serum. According to Levaditi and Yamanouchi, the lipoids serving for serum diagnosis not only exist in the liver, but in other organs, the brain and the red corpuscles.

They are probably complexes in which lecithin enters largely. The anaemia may, however, be due to interference with the functions of the haemopoietic tissues; in support of this is the fact established experimentally by Neisser, that the red marrow and spleen are especially rich in the virus. Since mercury can rapidly improve this blood dyscrasia, it is probable that it does so by arresting the development of the *contagium vivum* in these blood-forming tissues. In congenital syphilitic children haemoglobinuria may occur, and this may be due to the existence of a large quantity of the virus in the blood causing haemolysis of the corpuscles. Many authorities working at the subject of metabolism in syphilis have shown that the nitrogen metabolism is altered. "Von Boick, Stephanow, and Bjelakow found that the assimilation of nitrogen of food sinks, and the percentage of extractives increases considerably in relation to the urea." (Max Nonne). This would indicate an altered dissimilative metabolism. There is therefore considerable evidence to show that causes exist which render the organs of the body more vulnerable, not only to other infective agencies—for example, tubercle causing scrofula—but also to the evolution and development of neuroses and degenerations by a devitalizing influence on the tissues by the unloosening of lipid substances. We have now to consider how far do these researches, biological and bio-chemical, help us in determining the etiology of tabes and general paralysis.

ETIOLOGY OF TABES.

(*Tabes Dorsalis, Tabes Optica, Tabo-Paralysis, General Paralysis.*)

The Wassermann method of diagnosis has come to strengthen and confirm the belief of many neurologists like myself: "*No syphilis, no tabes.*" This was previously based solely upon statistics and observations relating to the etiology of the disease. Moreover, the etiology and the serum diagnosis are reciprocally supporting not only of the parasymphilitic theory, but also of the view that there is one morbid entity which may be described as tabes—a view first put forward by Fournier, and which I have supported by comparing the clinical notes, and in a large number of instances the *post-mortem* results (with microscopic investigation) of 60 cases of tabes dorsalis and 60 cases of tabo-paralysis. I came to the conclusion that Fournier was justified in asserting the identical relation of the etiology, the close relationship and overlapping in the symptomatology and pathology, and that he was right when he destined them one day or other to be grouped in a single pathological entity; for Ferrier, in his admirable Lumleian Lectures on tabes dorsalis, says: "... and here I would express in concurrence with Fournier, Mott, and many other neuropathologists of the present day, my belief in the essential pathological identity of tabes and general paralysis. They are, in my opinion, merely different aspects of the same polymorphic disease." Both are tabetic, or wasting, affections of the sensory protoneurons in the one case, and of the cortical neurons in the other. The essential etiological factor is the same, and the average time elapsing between the primary infection and the onset of the degenerative process corresponds in the two diseases. Fournier remarks that the establishment of the syphilitic origin of tabes dorsalis, from his experience, would necessarily end in the application of the doctrine to general paralysis. In fact, there are so many symptoms in common and so many analogies of evolution and termination associating these two diseases, that it was quite natural to conclude the etiology of one from that of the other.

I have endeavoured to show in the *Archives of Neurology*, vols. i and ii, and elsewhere, all the evidence of the etiology of tabes and general paralysis tends to prove that there is in all probability one essential cause—syphilis, acquired or congenital; and that there are a number of contributing factors, any one of which by itself, or even in combination with others—for example, sexual excess, mental stress, heredity, injury, etc.—is not capable of producing the disease. The fact that congenital syphilis leads both to tabes and general paralysis at so early a period of life as to exclude most of the contributory factors except heredity, is an argument in favour of syphilis being the essential cause. Moreover, males and females are affected with juvenile optic tabes, and general paralysis in equal

numbers. Thus, of 500 general paralytics that have died and been examined *post mortem* at Claybury, there were 5 males and 5 females who suffered with juvenile general paralysis; that is, 2 per cent. of the total. The study of heredo-syphilis in relation to these parasymphilitic affections is especially convincing as to the essential cause of tabes and general paralysis being syphilis. This has been brought home to me in a very convincing manner in the large number of cases in which I have studied the family histories. I will cite a few examples: A young man was admitted to Claybury suffering with what were termed epileptic fits; the seizures did not cease, and he died; externally there was nothing on his body to show that he had congenital syphilis: his liver, however, showed typical signs of congenital syphilis, and the brain was typical of general paralysis. A brother in Caterham Asylum presented the facies of a typical congenital syphilitic. I ascertained that the father died of general paralysis, and the mother, when I interviewed her, was in the early stage of dementia. I was asked to see recently at Hanwell a young girl who, blind from optic atrophy, had later become demented. I was informed there were no signs of syphilis on the body, and she was one of a large grown-up family. Fortunately the mother was there at the time. I therefore had the opportunity of interrogating her. I found it was quite correct that she was one of a large family, but I also ascertained that, prior to the birth of this child, there had been several miscarriages and stillborn children, that this child had suffered with snuffles and a rash, that she had taken it to the hospital, and grey powders had been given. When the rash disappeared she ceased to attend further. As so often happens in these cases, the mother had not apparently suffered, and showed no signs of syphilis.

Another example I may mention. A juvenile paralytic boy was admitted to Bexley and died there. Recently his brother has been admitted with commencing signs of the disease. The former had Hutchinson teeth, but no history of syphilis could be obtained from the father. This man died in Guy's Hospital. I wrote to the registrar, and I received the information that he had had syphilis. Perhaps the most convincing case is the following one, which died in Claybury about a year ago. A boy was admitted with dementia, contraction of all four limbs, and epileptic seizures. Dying not long after admission, the *post-mortem* examination revealed very advanced general paralysis. There were no signs on the body, and the boy up to 12 years of age was bright and intelligent, then mental symptoms set in and steadily progressed. A history from the father showed that five years before marriage he had contracted syphilis, and, in spite of long treatment by an eminent physician, had not been cured, for the first child died within forty-eight hours of birth, the second within twenty-four hours, the third suffered with late interstitial keratitis, and later nerve deafness; then came the patient, and afterwards healthy children. I could multiply these instances, for altogether I have notes of some 60 cases, and in the great majority (over 80 per cent.) there are indubitable signs or an unquestionable history, as in the above cases, pointing to hereditary syphilis. I have found no case in which I could *certainly* exclude syphilis. Particularly common is optic atrophy, which takes these children to the blind school, and there they develop fits or signs of mental deterioration, and are next sent to the asylum.

The cases of tabes occurring in heredo-syphilis are not nearly so numerous as the cases of general paralysis; the ataxy is usually not very marked, optic atrophy is very common, and tabo-paralysis is met with often associated with optic atrophy; optic atrophy occurs also pretty frequently in the paralytic dementia of congenital syphilis. I have seen two brothers so affected, and die after developing the signs of progressive dementia.

The period of time elapsing between the evolution of tabes and general paralysis and the acquired infection varies considerably; it may be from three to thirty-one years; but the average is eight to fifteen years. The life of the neurons has been reduced, and the time that will elapse between infection and the onset of decay depends upon the intensity of the virus and the inborn resistance of the nervous system, together with other supplemental factors causing stress. In these hereditary cases it is surprising how frequently we find one of the parents, and occasionally both, suffering

from paralysis or tabes; this implies an inborn tendency to this degenerative condition. Now it may be asked, if twenty-five years, or even more, can elapse in an adult between the acquirement of syphilis and the onset of the symptoms of parasyphilis, why should not the same long period occur occasionally in congenital syphilitic cases, so that instead of the first symptoms commencing at puberty they are not manifest till adolescence, or even considerably later? Nonne relates a case of a workman, aged 32, who had suffered for two years with lightning pains and had never been infected with syphilis or addicted to drink, and who presented all the typical signs of ataxy. He had been treated in the hospital for severe hereditary syphilis. I have seen a somewhat similar case; moreover, I have occasionally observed similar cases of general paralysis—for example, a man aged 28 died recently in one of the London County Asylums of very advanced general paralysis. The disease was first manifested at the age of 18, when he had a fit. His character was strange; he married, had one child born dead, and afterwards his wife left him. He had no signs of syphilis on his body, but I found that his father had died eight years previously in Claybury Asylum. In my Croonian Lectures upon the Degeneration of the Neuron, I remarked that it is very probable that some of the cases occurring in adults in which syphilis can with certainty be excluded, may still owe the disease to an inherited syphilitic taint. It is not even necessary, as quite one-half of the juvenile cases show, that they should exhibit any external signs of congenital syphilis, for many of the juvenile cases which I collected were proved beyond doubt to be born of syphilitic parents, although manifesting themselves no external signs of syphilis, whereas brothers and sisters exhibited very definite signs. A case of general paralysis died at Bantstead Asylum which had previously been under the care of Dr. Percy Smith at Bethlehem Hospital. This woman had characteristic signs of congenital syphilis, but she did not manifest symptoms of progressive dementia till she was 30 years of age. The patient was an unmarried woman, and there was no reason to believe that she had acquired the disease. Recently Christian Müller has put forward the same hypothesis to explain those cases in which no history of acquired syphilis can be obtained. He describes two cases of women (virgins) who were the subjects of well-marked signs of congenital syphilis, and who died of general paralysis at the ages of 42 and 43 years. The symptoms were not noticeable until a year or two before death.

Dr. Ferrier has in a masterly manner reviewed the evidence which points to syphilis being the essential cause of general paralysis and tabes, and, in conclusion, I cannot do better than quote him: "One might multiply arguments in favour of the causal relation between syphilis and tabes, but they are unnecessary. For those above related, singly and collectively, leave, in my opinion, little room for doubt that tabes and general paralysis are in all cases of syphilitic origin, and that tabes, *per se*, is as much a proof of antecedent syphilis as a gumma of the skin."

Although syphilis is the essential cause, yet, as Fournier showed, tabes and general paralysis are not syphilitic, but an outcome of syphilis, and the riddle is still unsolved why only about 3 to 5 per cent. of the persons infected with syphilis should subsequently suffer with one of these degenerations of the nervous system termed parasyphilitic. But only 10 to 15 per cent. of persons suffering with diphtheria develop post-diphtheritic paralysis; these are usually cases in which the local infective process was mild and often unnoticed; in that respect, like parasyphilitic affections, which more often than not follow mild and even unrecognized primary infection and secondary symptoms. Is it because the virus is attenuated or modified, and thereby has acquired a special neurotoxic action, or is it because in a small percentage of individuals the cells of the body, especially the cells of the nervous system, react to the virus in a hypersensitive manner? As already indicated, there are facts which suggest the possibility of a certain form of virus with a neurotoxic action. Thus Babinski remarks that it seems possible that a syphilitic virus may sometimes be endowed with a particular aptitude for attacking the nervous system; he reports the case of two students who were infected the same day by the same woman; both died fifteen years later of general paralysis; these students were, however, related. I have recently heard of two pro-

fessional men, not related, who acquired syphilis about the same time from the same nurse; ten years later they developed general paralysis. Marie and Bernhard relate the instance of two men who were infected from the same source, and ten years later suffered with tabes. Erb narrates an instance of four patients infected by the same woman, who later became the subjects of either tabes or general paralysis, whilst a fifth, who had connexion with the woman but was not infected, did not suffer with any disease later. Probably the most striking example supporting this theory of a special neurotoxic virus has been afforded by Brosius, who relates that seven glass-blowers suffered with chancre of the lip, and out of five who ten years later came under observation, four suffered with either tabes or general paralysis. If we accept the fact that a spirochaete is the specific causal agent of syphilis, it is conceivable that there may be varieties of this organism, as there are of the malarial parasite or trypanosome. Again, the organism may become attenuated or modified in its passage through the bodies of certain individuals, or it may be attenuated or modified by the action of mercury. It may thus happen that the virus may vary in different cases of infection. This, however, is speculation, and is not supported but rather contraindicated, so far, by experiments on animals. For although lower apes have the disease in a mild form when inoculated from the human being, yet the syphilitic virus of an infected *Macacus rhesus*, when used to infect a chimpanzee, appears to have lost none of its original virulence; for the chimpanzee suffers as badly as if it had been infected direct from the human source of the virus. We are probably, therefore, on more certain ground in attributing the variation of the effects which will follow infection not to the variation of the virus, but to the reaction of the individual himself, and we may represent this in the form of an equation:

$$\text{Symptom complex } x = \frac{V}{R} = \frac{\text{virus}}{\text{resistance}}.$$

If the virus V is constant, R resistance must vary. But R is made up of a number of factors, some of which we can ascertain, but it is generally impossible to decompose R into all its constituents. Roughly speaking, we may say that it is made up of what a man is born with, what has happened after birth, and what will happen in the future to resist the reaction of the specific virus, which in the majority of instances is of lifelong duration. Most authorities agree that with the widespread syphilization of a race for many generations, the disease tends to assume a milder form; the effects of the disease are not so severe, and a widespread tendency to an inherited immunity has been brought about. The conversion of a rural into an urban population has done much towards racial syphilization and to the diffusion of a tendency to inherited immunity, and the begetting thus of a mild form of disease. But, whereas there are fewer cases of severe syphilis than formerly, there are more cases of tabes and general paralysis. The interesting description given by Colonel Lamb of the syphilization of the natives of Uganda shows how severely a race previously free from this disease suffers from malignant skin, bone, and visceral disease. He also points out that tabes is very rarely seen. If we consider some facts concerning congenital syphilis, we must come to the conclusion that immunity is possible; how, otherwise, can we explain the law of Profeta, namely, the non-syphilitic child of a syphilitic mother does not acquire syphilis from the syphilized mother who suckles it? Again, the child may be syphilitic and the mother may show no signs of syphilis; the mother does not acquire syphilis by suckling that syphilitic child, whereas a wet nurse does. In the former case the fetus has acquired some antitoxin, or something from the maternal blood which has stimulated its own tissues to react against the virus; in the latter (Colles's law) the mother has derived from the blood of the syphilized child an antitoxin or something (not the living contagium) which has stimulated her tissues to react against the virus so effectively that she cannot be infected. There is no reason to suppose that the germ cells do not participate in this reaction, seeing that every cell in the body is subjected to the sensitizing influence of the chemical products of the virus by means of the blood and lymph. The experiments of Ehrlich have been quoted by Neisser as opposing the view of inherited immunity; on the

other hand, Conradi's recent experiments on lyssa support it. The histories I obtained in a large number of cases of juvenile general paralysis and cases of congenital syphilitic nervous disease revealed the fact that the mother very frequently had miscarriages, abortions, and typically syphilitic children without herself suffering at all, or presenting any signs of syphilis. In two instances the mother died of general paralysis; in a considerable number of instances the father died of this disease. As a general rule, the result of successive conceptions is as follows: Miscarriages, abortions, dead children, children dying in infancy—often of meningitis or hydrocephalus—children who later in life suffer with nervous affections—for example, nerve deafness, paralytic dementia, optic atrophy, and tabes—and, finally, healthy children. Such a chain of circumstances would undoubtedly indicate that either the virus was becoming attenuated or the resistance of its action was increased. In any case, we have reason to suppose that the children who were born with a syphilitic rash would be immune to reinfection, also those who afterwards suffered with parasymphylis; Kraft-Ebing's observation supports this premiss. It is probably a question of the degree of immunity to reinfection that would obtain in the presumably healthy children that followed the diseased ones. But such a chain of events does not always occur, for sometimes children are born with signs of heredo-syphilis after the birth of several healthy children: also parasymphylitic children may be born after the birth of several healthy children. This may be explained by the fact that the specific virus has become active again in the mother, which inference is negatived in most instances by the fact that she herself may say that she has been in good health, and no signs of the disease can be discovered in her. Another explanation offers itself, and it is that the specific virus may have attacked one ovum and spared another. Levaditi has seen the spirochaete within an ovum. No two individuals, even of the same family, are born alike, because the germ-plasm out of which they were formed may be similar, but is not the same; one inherits ancestral tendencies which the other does not; and it may happen, therefore, that a child born later than the healthy children possesses less inborn resistance to the action of the virus; consequently, manifests congenital syphilis or, later, parasymphylis. How can we explain this process of decay of particular groups, systems, and communities of neurons? Why should we have optic atrophy in one individual, atrophy of the spinal portion of the sensory protoneurons in another, decay and atrophy of the cortical neurons in a third, and, in many instances, a decay and atrophy of the whole nervous system? We cannot suppose that it is caused by the random metastasis of the syphilitic organism in the membranes, or coats of the blood vessels, conveyed by the lymph or blood stream, as is probably the case in the true syphilitic lesions of the brain and spinal cord. Everything points against this, for, although parasymphylitic affections present the most varied signs and symptoms, there is one sign usually present which is, for all practical purposes, only met with in parasymphylis, namely, the Argyll Robertson pupil. No coarse random lesion will explain the constancy of this phenomenon; moreover, this condition, although a sign of syphilitic infection, does not occur in true syphilitic brain disease. Spirochaetes have never been found in the cerebro-spinal fluid nor have antigens. Antibodies are found proportional to the extent of neuronic decay in tabes and general paralysis.

I think all the facts are against the views of Lesser, Bose, and others, that these late manifestations of degeneration of the nervous system may be regarded as quaternary syphilis, a very late effect of the virus comparable with syphilitic ophthalmitis, glossitis, and other sclerotic lesions. According to this view, we should be compelled to consider the meningeal and perivascular infiltrations and the glia cell proliferation as the cause of the degeneration. But there are many reasons why we cannot accept this hypothesis. The view I take of the process is that parasymphylitic disease of the nervous system depends upon two factors, intrinsic, innate, and extrinsic, acquired—the soil and the seed; the vital resistance and the specificity of the virus, V.

All those conditions which may be inherited or acquired,

which tend to active metabolism of systems, communities, and groups of neurons functionally correlated, owing to those conditions of stress causing in one individual spinal neurasthenia, in another cerebral neurasthenia, will, in conjunction with the effect of the syphilitic poison, cause the nerve cells to exercise an abnormal dissimulative metabolic activity.

Ehrlich points out that we cannot suppose that the cells of the body possess *per se* an executive defensive capacity to neutralize the noxious effects of all forms of organisms, and his work on haemolysins shows that the haemolysin for the corpuscles of a particular animal only occurs after incorporation of the molecules of those corpuscles. But we may suppose that there is an inherent aptitude for the cells of the body of certain individuals to adapt themselves readily to defence against the action of the syphilitic virus in a race that has been widely syphilized for generations; consequently, a larger number will have a mild form of the disease. Cases of tabes and general paralysis occasionally arise within three years of the primary sore; possibly this may be due to an inherent hypersensibility to react to the poison. Dr. Byrom Bramwell has recorded a remarkable case of tabes which came on ten months after infection; it would be interesting to investigate the family history and past personal history of these cases to ascertain whether or not it was a second infection.

The nerve cells are perpetual elements incapable of regeneration, highly differentiated, and complex in structure and function; their centre of nutrition is the nucleus, and when decay sets in, the regressive process attacks first the fine twigs and branches of the tree, the dendrites and dendrons, and the rootlets; in fact, the process is an inversion of its growth and development. But what should cause this premature decay and lack of durability, for the specific energy of the whole of the neurons in the healthy body is sufficient to last until the vital spark dies out? We know the more prolonged duration of infectivity of the syphilitic virus as compared with other contagious diseases, also that one attack of syphilis confers immunity during the rest of the individual's life; moreover, the experiments of Kraft-Ebing are important to remember in this respect. The nerve elements being perpetual and having acquired a habit of increased metabolic activity, will continue it during life, and will contribute to the excess of lipoids in the blood. When there is no longer metabolic equilibrium, and decay sets in, these lipid proteid complexes are thrown off in increasing numbers; this seems probable from the fact that in general paralysis and tabes the quantities in the cerebro-spinal fluid increase with the progress of the decay. The process of decay will manifest itself in the earliest stages by an increased irritability and functional activity of the nervous structures, often manifesting itself in a *hyperaesthesia sexualis*, emotional exaltation and, not infrequently, in striking intellectual activity, followed in each case by exhaustion and loss of function. In my second lecture I referred to the fact that the lipoids may be products of nuclear activity and the highly phosphorized nuclein may be really the source of vital action. We can, therefore, understand how detrimental a *hyperaesthesia sexualis* is to the vitality of the body by the fact that it occasions a loss to the body by the sperm of nuclein substances highly charged with phosphorus.

The uselessness of antisymphylitic remedies is thus accounted for; indeed, they are generally positively injurious in true tabes and general paralysis because they lower the vital energy of a system which has over-immunized itself against the syphilitic virus. The only hope of doing any good is by an early diagnosis of the disease and suppression of all those exciting causes which use up the nervous energy and tend to overturn the normal metabolic equilibrium of the nervous structures. Other factors come in, determining the location of the degeneration, and although microbial infectious and microbial toxæmias are not directly responsible for these parasymphylitic affections, yet they may be an exciting agent in the onset of the disease to the aggravation of the symptoms and the acceleration of the progress of neural decay and the fatal termination. I have often observed when influenza, dysentery, or pneumonia were prevalent in the asylums a number of general paralytics died after a succession of epileptiform or apoplectiform

seizures, and I have found, *post mortem*, that they were suffering from one of these morbid infections. It is a common thing to find on the *post-mortem* table patches of bronchopneumonia, the appearances of which would accord with clinical notes in the case-book reporting the occurrence of seizures; and, if the brain be examined microscopically, it is easy to prove that these fits may correspond with acute degenerative changes, doubtless caused partially by congestive stasis and partially by a toxic condition of the blood exciting and accelerating the process of neural decay. Bacterial invasion, *secondary or terminal*, of the organs of the body of a *non-specific* nature, therefore, may accelerate the morbid process of decay or bring about a fatal termination.

In conclusion, I thank the Fellows for their kind attention, for I am not unmindful of the fact that many distinguished men have preceded me in the delivery of the Morison lectures. I feel that I have dealt imperfectly with a very difficult albeit important subject still in its infancy; and I can only hope that the words of the old philosopher, Lucretius, may come true, "that one thing after another will grow clear, and dark night will not rob you of the road, to keep you from surveying the utmost things of Nature; in such wise things will light the torch for other things."

A CASE OF ACUTE ASCENDING PARALYSIS.

By HENRY J. DEAN, L.R.C.P., L.R.C.S., L.S.A.,

WILLENHALL, STAFFORDSHIRE.

LANDRY'S disease is sufficiently uncommon to make the report of a case which recently came under my care worthy of publication.

The patient, a man aged 24 years, had had no illness during the last few years, except an occasional cold, which did not incapacitate him from work. He got wet cycling a week previous to my seeing him, but followed his occupation during the next four days and did not feel at all unwell; on the fifth day he remained at home complaining of vague pains and a feeling of general weakness. He did not improve, and I saw him two days later.

I found him sitting on a couch downstairs still complaining of pains in his shoulders, legs, and back, the latter being the most severe and referred to the sacral region. He also complained of a feeling of numbness from the middle of the body down to the feet and of weakness in the legs, but there was no definite pain, nor at this time any definite paralysis. He could rise up from the couch and stand or walk without assistance, but said he did not feel safe on his feet. There was no difficulty in breathing or swallowing, and no rise of temperature. The knee-jerks were entirely absent.

The next day he still had pain in the back and said it felt weak, and the weakness in the legs had progressed to a definite paralysis, so that he could not get up or stand without assistance, and his feet were affected to about the same extent, but, judging from the slight motion remaining, the posterior muscles were paralysed to a greater extent than the anterior. He was unable to turn over in bed and felt easier in a chair, where he sat huddled up, often requiring support to maintain his position or help in changing it. He now complained of some weakness in the arms, and his voice was weak

and husky; he had some difficulty in clearing the throat, and cough was wanting in energy, and there was some difficulty in swallowing. The abdominal muscles were flaccid, and seemed to have lost power, and probably the intercostals, the quadratus lumborum, and the muscles of forced expiration were beginning to share in the paralysis. The movements of the chest were impaired, but there was no dyspnoea. Sensation in the paralysed parts was unaffected: he could feel the slightest touch of a pin on the finger, and pain when pricked with a pin. The muscles felt of normal firmness, and were not tender when handled.

On the third day the paralysis had rapidly extended; the legs were almost motionless, but he was still able slightly to extend them at the knees. He begged to be out of bed, and sat more huddled up from paralysis of the back and abdominal muscles, and had to be supported by pillows, or, when I saw him, by a friend on either side. He was unable to raise the arms at the shoulders, but could flex and extend the elbows, although not able to hold a cup with his fingers or to carry it to his mouth. His head hung forward. He spoke in a whisper, but beyond that the speech was not affected, and no paralysis of the tongue, lips, or face was observed. The loss of voice was probably due in a great measure to paralysis of the expiratory muscles. He had great difficulty in clearing the throat of secretion, the power to cough and all expiratory efforts being almost entirely lost. There was much trouble in swallowing, but no regurgitation of fluid through the nose, and the soft palate, as far as could be judged, was not affected, the dysphagia being due to paralysis of the muscles presiding over the act of swallowing. He was able to swallow small pieces of jelly better than liquids. He had no marked dyspnoea and no violent respiratory struggles. No ocular paralysis was observed. About 11 p.m. he was almost asphyxiated by the accumulated secretion in the throat which he was unable to expel.

On the fourth day I found he had passed a very bad night, the secretions in the throat causing much distress. He could not clear his throat, and swabs or sponges had to be used. He lay almost motionless, and during the day became rapidly worse. The movements of the chest were quicker and feebler, and the paralysis affected the respiratory muscles—pharynx and larynx more and more. Swallowing became exceedingly difficult, but he was able to take a little jelly, but no nasal fluids were quite clear, and down to this time the temperature was never half a degree above normal. At 10 p.m. it rose to 102°.

He died quite suddenly about 1 a.m. next morning. About half an hour before death the sphincter became paralysed and he passed faeces involuntarily. There was no convulsion or struggling, and his mental condition was quite clear to the end; in fact, he made himself understood to the nurse within a few minutes of death, which appears to have been due to asphyxia.

No treatment seemed of any avail. An autopsy was not obtainable.

The chief features of the case, apart from its rapid progress, were:

1. No obvious cause, beyond getting wet.
2. Absence of knee-jerks from the onset, before any actual paralysis was noticed.
3. No rise of temperature until within three hours of death.
4. Sensation unimpaired, the only sensory symptoms being numbness and vague muscular pains.
5. Perfect consciousness of his state to the end.
6. Rapidity with which the paralysis affected the acts of coughing, all expiratory efforts, and swallowing.

With regard to the order of invasion, after the feet and legs became paralysed the progress of the disease was so rapid that it was difficult to follow the exact sequence, except (a) the posterior muscles of the legs and thighs appeared to be affected before the anterior or to a greater extent, and (b) the muscles moving the upper arm on the scapula before those of the forearm.

As a note of distinction from acute disseminated myelitis I would mention (1) the absence of anaesthesia or any impairment of sensation; (2) normal temperature except just before death; (3) the freedom of the rectum and bladder until within half an hour of the end.

The reports on the therapeutic results with radium which have come from Germany seem scarcely so optimistic as those from Paris. Dr. H. E. Schmidt of Berlin (*Jahrbuch über physikalische Medizin*, p. 193) says that in all cases of naevus treated by him he has always found a tendency in course of time for the redevelopment of telangiectases, generally some months after the discontinuance of the treatment, and he believes that in such cases treatment by Finsen light or electrolysis is necessary to complete the cure. He speaks of one specially good result which he obtained in a case of naevus pigmentosus pilosus in a child. The growth was on the left cheek, about the size of a shilling, dark brown, and hairy. After prolonged treatment the naevus disappeared, leaving only a not very noticeable scar, but here and there dilated vessels began to appear in it, yet by following up the cure with Finsen-light treatment most of these dilated vessels were removed, and the final result was very good.

ARTERIAL BLOOD-PRESSURE RECORDS BEFORE AND AFTER MUSCULAR EXERTION.

By O. K. WILLIAMSON, M.A., M.D., B.C. CANTAB.,
M.R.C.P. LOND.,

PHYSICIAN TO OUT-PATIENTS AT THE CITY OF LONDON HOSPITAL FOR
DISEASES OF THE CHEST, VICTORIA PARK, ASSISTANT PHYSICIAN
AT THE EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL.

THERE exists a remarkable divergence of expert opinion on the question as to whether the results of systolic arterial blood-pressure readings by the method of circular compression represent in all cases the true blood pressure. Those who hold the opposite opinion consider that, more particularly in cases where these readings reach the higher limits which are met with—say from 200 to 300 mm. Hg—the manometric index records something beyond the pressure of the blood itself; in other words, that a part of the force spent in obliterating the lumen of the vessel is due to the resistance of the arterial wall itself. Whilst the majority of those who have worked in this domain of clinical medicine favour the former view, yet several observers—among whom may be mentioned Drs. William Russell, George Oliver, and W. P. Herringham—have given reasons for dissent from the prevalent opinion.

It would seem that light may be thrown on the question, even though we cannot hope thus to actually prove the matter, by observations taken before and after violent muscular exertion in healthy men, seeing that it can hardly be maintained that the blood-pressure readings as measured after such exercise can be influenced by the resistance of the arterial wall. For, in the first place, there is in such conditions a state of vaso-dilatation, so that the effect of hypertonic contraction can be excluded, and, secondly, it is premised that the subject observed is free from arterio-sclerosis. If, then, on the one hand, as the result of muscular exertion of this kind, a considerable arterial blood pressure should be reached, this would point to the possibility of an equally great height being attainable as the result of disease; but if, on the other, but a moderate elevation—say well below 200 mm. Hg—be met with, this would afford even stronger evidence of the improbability that the heart in morbid conditions would be capable of overcoming pressures much greater than this.

The only observations made on these lines which I have met with in the literature are as follows:

T. C. Janeway found, in an experiment with the Erlanger apparatus (5 cm. armlet), on a healthy young man of 26 years, a rise of pressure after he had run up three flights of stairs = 40 mm. systolic and 20 mm. diastolic, the observations being taken during the sitting posture.¹

W. Russell says²: "I submit that the 20 mm. rise after violent exercise marks the limit of the reserve of power of the normal average heart."

K. A. E. Fries made observations on the pulse and blood pressure in foot-racers.³ He determined the pulse-rate and blood pressure in athletes in races of various lengths, using the Recklinghausen-Landergren modification of the Riva-Rocci sphygmomanometer to measure the latter. In general he finds that the pressure rises during the first 35 to 40 minutes of running (10 kilometres), and then falls to considerably below its original level. After one English mile the rise might be from 10 to 40 mm. Hg, the pulse then beating 120 to 160. After a "Marathon" race (40.2 kilometres) the fall below the pressure at starting might be from 10 to 20 mm. Hg.

It may be urged in criticism that the mere fact of this compensatory vaso-dilatation during severe exertion lessens the work of the heart, and therefore renders my argument of little value, seeing that in disease there is frequently vaso-constriction. It is doubtful, however, how far this argument is a sound one.

My own observations were of two kinds. Through the courtesy of several of the competitors for the *Evening News* Marathon race last autumn I was enabled to make observations on them immediately before and after practice runs varying in distance from 5 to 13 miles. Secondly, I made observations on three hospital residents before and after they had run quickly down and up several flights of stairs. The results confirm in the main the observations quoted above.

Four competitors for the Marathon running race were examined. Oliver's haemomanometer was the instrument used (a modification of the Riva-Rocci method). The observations were taken on the arm, this being of course at the level of the heart, and the subject being in the sitting posture. The first observations were taken in every case immediately before the competitor started his course, and the last directly after he had finished (within a minute approximately). The details are given in the table at the foot of this page.

The readings of diastolic pressure and pulse were only approximate. Nos. I, II, and III were, apart from some cardiac hypertrophy, healthy men. No. IV exhibited some thickening of the superficial vessels and cardiac hypertrophy. No. I was very slightly dyspnoeic at the time of the second observation. No. II stopped running on account of his leg "giving"; no signs of exhaustion. No. III was dyspnoeic at the time the second observation was made, and seemed somewhat exhausted. No. IV was likewise rather dyspnoeic. The weather was very hot at the time of all the observations. It will be seen that three of the cases showed a rise of from 25 to 28 mm. systolic pressure, the diastolic either remaining constant or rising to a less degree. One case (No. II) showed a fall of systolic pressure. The observations on the hospital residents were taken under similar conditions to the others, the first being made in each case before the subject started running down and up several flights of stairs, and the last directly after he had finished (within about a quarter of a minute). The observations were taken on the forearm.

		Before Exertion.		After Exertion.		Difference between Systolic Pressures.	Difference between Diastolic Pressures.
		Syst.	Diast.	Syst.	Diast.		
No. I.	Mr. P. M., 24 yrs.	115	100	152	—	37	—
No. II.	Mr. A. J., 28 yrs.	120	95	138	90	18	-5
No. III.	Mr. C. W., 23 yrs.	135	99	145	90	10	0

Syst. = systolic pressure. Diast. = diastolic pressure.

The diastolic readings were only approximate. No. I ran three times up and down stairs, No. III twice, and No. II once. Nos. I and III were markedly dyspnoeic as the result of the exertion; No. II was less so. At the time No. I ran the weather was very hot. The results show a rise of from 18 to 37 mm. systolic pressure.

CONCLUSION.

My results point to a rise of from 20 to 40 mm. Hg, corresponding to a height of perhaps 160 to 170 mm. as the measurement which is probably near the limit of reserve power of the normal heart. Consequently these observations at least throw doubt upon the idea that readings obtained in the neighbourhood of 300 mm. really represent true blood pressure.

THE TREATMENT OF CHRONIC GONORRHOEA BY ANTIGONOCOCCAL VACCINE.

By ARTHUR LOXTON, M.B., F.R.C.S.E.,

SURGEON TO THE BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND
URINARY DISEASES.

THERE appears to be a general consensus of opinion that for systemic gonorrhoeal infection, the hypodermic injection of known doses of dead gonococci is the most effective means of treatment; but, so far as I know, no one has yet published his experience of treating chronic gonorrhoea by this method.

For the last twelve months I have been treating obstinate cases of gonorrhoea in this way, and I am persuaded that for certain cases it is most valuable. As yet I am by no means prepared to say the method is invariably curative, but with experience I believe its value will become very greatly enhanced.

The constitutional disturbance caused by the injection varies with the temperament of the individual. In a highly-strung man it may be so severe as to cause him to refuse further treatment, while in a phlegmatic individual who has confidence in his doctor, appropriate doses only give rise to slight headache and malaise some hours after the injection. For this reason it is a good plan to inject the vaccine in the late afternoon, so that business may not be interfered with, and discomfort deferred till bedtime, when the patient may sleep it off. Experience shows that to get any good effect from inoculation two or three points must be attended to:

(a) The gonococcus should be demonstrated in the urethral discharge. It is obviously of no use to inject antigenococcal vaccine if the gonococcus has died out and the discharge is perpetuated by other forms of bacteria.

(b) It is useful to get a patient into a good state of health before commencing the treatment. This may be accomplished by means of a holiday or the exhibition of iron.

(c) It is most important that the dosage be carried out systematically. I find that the best results are obtained by commencing with small doses—forty or fifty millions of sterile gonococci—and, as the patient becomes accustomed to the treatment, rapidly to increase the inoculation. This may be done in two ways—either the number of organisms may be increased or the interval between the doses may be shortened. A judicious combination of the two gives the best results.

I will briefly relate 3 cases in illustration:

CASE I.

In October 1905, a gentleman, aged 27, contracted syphilis, and in July 1906 a urethral discharge was present in which I failed to find gonococci. In August, 1907, the patient again contracted urethritis, and the gonococcus was present in large numbers. This attack ran a prolonged course. Time after time the discharge was reduced to a minimum, but the slightest departure from strict teetotalism was immediately followed by relapse, and gonococci could always be demonstrated in the discharge. He was under continuous treatment during January and February, 1908, yet on March 11th gonococci were plentiful. He then submitted to injection of vaccine, and had five injections, the last being on May 12th. The discharge diminished from the first, diplococci disappeared, and the patient was cured. Quite recently I met this gentleman, and he says that he dines, goes to smoking concerts, and other amusements, places no restriction on himself, yet remains quite well.

CASE II.

Last September a gentleman sought my advice on account of what he believed to be a long-standing urethral discharge. In 1904 he suffered from gonorrhoea and was under treatment for some months. He believes he has never been quite well since. His account now is that ten days after exposure to infection he noticed a small amount of discharge first thing in the morning. He cured this himself, but after drinking a few glasses of beer the discharge returned. He received the usual treatment till October 7th, when, as I was able to see diplococci in the discharge, I suggested antigenococcal injection, and gave him at once 0.5 c.cm. of the Lister Institute vaccine. On October 20th I injected 1 c.cm. and no further discharge was observed. As a precaution the 1 c.cm. was repeated on November 3rd and 16th. On December 3rd I examined the patient and could find nothing wrong, and a week or two ago he wrote to say he was quite well and leading his ordinary life.

CASE III.

This case illustrates the advantage of rapidly increasing the dose. Last April a gentleman, 30 years of age, consulted me for gonorrhoea. He had had several attacks, and probably had

not been quite free for some years. He was under treatment till the end of July, when he was advised to take a holiday. In October he returned to me and said that, although he was better, he was not well; he had to refrain entirely from alcohol, or he suffered from an annoying discharge. Gonococci were recognized, and on October 7th 0.5 c.cm. antigenococcal vaccine from the Lister Institute was injected subcutaneously, on October 23rd 1 c.cm., and on October 31st 1 c.cm. These injections caused no constitutional disturbance, and the patient was better. On November 23rd he came again, saying that he had been to a dinner party, had drunk wine moderately, and the next morning had again seen some discharge. On December 7th gonococci were once more demonstrated, and as the previous injection had not caused any marked discomfort, I advised the patient to have a few injections at short intervals, and of increased dosage. Accordingly, on December 11th I injected 1 c.cm. antigenococcal vaccine, on December 17th 1.75 c.cm., and on December 21st 2 c.cm. The patient went away to spend Christmas at a seaside hotel and was snowed up, so that his holiday was passed almost entirely indoors. He placed no restriction upon himself as regards smoking, eating, or drinking, and has suffered no return of his complaint.

These cases show that in the hypodermic injection of sterile dead gonococci we possess a curative agent which in all probability will prove to be of marked service in the treatment of gonorrhoea. If this surmise proves to be correct, it is a method which deserves to come into general use, because the way it brings about a cure is the most rational with which we are acquainted. At present we have no other means of attacking the gonococcus directly. Our injections, or drugs administered internally, can only act indirectly upon the organism; but if we can produce in the juices of the body a substance which is a poison to the gonococcus, then we may hope that the disappearance of the signs of the disease thus brought about means that the gonococci are killed, and not merely hidden away in a quiescent state, ready to light up again when an opportunity presents itself.

The antigenococcal vaccine prepared by the Lister Institute is a convenient and reliable preparation with which to make the injections. The gonococcus is such a delicate organism, and so difficult to grow, that unless one has a laboratory in one's consulting room the attempt to manufacture a vaccine from the individual case is almost certainly doomed to failure.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A PLEA FOR MORE ACTIVE TREATMENT OF ACUTE GONORRHOEA.

THE treatment of a case of gonorrhoea is surrounded with difficulties, and it can hardly be gainsaid that in this country it is only too often carried out imperfectly and attended with indifferent success.

Within the last four years I have had under my care 19 cases of acute gonorrhoea, and facilities were available for their efficient and thorough treatment under my supervision. The treatment I invariably adopted was briefly the early and repeated irrigation of the anterior portion of the penile urethra without the administration of any specific internally.

I have been in the habit of directing the patient as follows: Ten ounces of a solution of boiled water allowed to cool to a comfortable temperature, 99 to 100° F., to which has been added a grain of potassium permanganate, is allowed to flow into the urethra from a douche can, to which is connected a length of tubing and a suitable glass or bone nozzle. The patient is directed to grasp the penis between the index and middle fingers of the left hand, so as to shut off the anterior $\frac{1}{2}$ in. of the penile urethra, the douche can is raised to a height to ensure a moderate pressure of fluid and the flow started and stopped by means of a convenient clamp on the rubber tube. Failing a douche can, a strong syringe with a ring at the end of the piston might be used; a syringe of this character can be easily manipulated by the right hand. Urination is to be performed when possible prior to irrigation. These irrigations are repeated hourly or oftener (three to four times in two hours) during the day, and at night also if this can be effected without disturbance of natural rest.

The boiling has already rendered the water sterile, so that the addition of a small quantity of potassium

permanganate is for effect rather than for its therapeutic virtues. With the exception of occasional saline aperients, and other hygienic measures, no further treatment is required.

This treatment has in my hands been rewarded with invariable success, the discharge disappearing even in the severest cases within ten to seventeen days; moreover, during the period of treatment all the distressing symptoms, such as chordee, priapism, and painful micturition, are mitigated. The degree of comfort enjoyed by the patient is an encouraging contrast to the distress which usually characterizes this malady; further, no complications have arisen in the whole series of cases treated by this method.

I was led to adopt this method of treatment on the grounds: (1) That the infection is primarily confined to the very foremost part of the penile urethra. (2) That local treatment is as rational when applied to the urethra in a condition of catarrhal or suppurative inflammation as it is when applied to a purulent ophthalmia and pyorrhoea alveolaris, and similar affections of other mucous membranes. (3) The restriction of the irrigation to the anterior part of the urethra precludes the risk of infection of the healthy membranous and prostatic portions. (4) At the same time there appeared no reason to complicate a simple procedure by including the whole urethra and bladder in the operation, as advocated by some authorities. It is no exaggeration to say that such grave complications as cystitis, orchitis, epididymitis, have been excited by the dissemination of the virus in the method of vesical and urethral irrigation. (5) Despite the fact that the organisms are intracellular and may be in the deeper layer of the mucous membrane, and bearing in mind that the infection is generally a mixed one, the washing out of the debris prevents further reinfection, and the temperature of the fluid used leads to an engorgement of the neighbouring vascular area with accompanying serous exudation, and this, presumably by virtue of its opsonizing properties, reinforces the natural resistance of the tissues to bacterial infection, much in the same way as a fomentation acts on an inflamed area. (6) Internal treatment is unnecessary: the patient is saved from the usual unwholesome therapeutic agents, which so often give rise to gastric derangement and consequent lowering effects.

It may be said that the practical difficulty of carrying out this method is so great as to preclude its adoption, but in view of the many complications of this disease involving serious crippling and even loss of life. I would point out that, in the case of those patients whose circumstances allow an interruption of business, it is the duty of the medical attendant to ensure that the position of his patient is such as to enable treatment to be immediately and strictly carried out. The patient should be sent to some home spa, where nursing homes with male attendants might be provided. By so doing success is ensured and a journey to a Continental doctor, after prolonged desultory treatment, as so often happens, is obviated. In the poorer class the patient should, where possible, be induced to seek admission to the Poor-law infirmary. The absence of appropriate institutions for the treatment of venereal cases, which under the present social conditions must inevitably arise, is a deplorable fact.

Sierra Leone.

GONORRHOEAL RHEUMATISM DIAGNOSED HYSTERIA.

The following case may prove of interest to your readers. The patient, a married lady, aged 24, who had had no children, no miscarriages, and no previous illnesses, except measles when a child, consulted me on account of pain "all over the top of the head." Her profession, the stage, entails an amount of facial gesticulation, and she informed me that whenever she wrinkled her forehead or raised her eyebrows, the pain was severe. She described it at that time as being of a sharp, stabbing character, and she experienced the same pain when she was dressing her hair or putting on her hat. When the scalp was at rest it felt tender, and there were occasional twinges, and all the time "she felt it was there." She had been rigorously treated for neuralgia with no beneficial

result, and had finally been informed that the condition would get better in time, that it was a form of hysteria, and that she had better try to forget it.

Upon examination the scalp was found to be distinctly tender to the touch, movement was evidently painful; there was a slight erythema and a scarcely appreciable amount of oedema or "puffiness," which the patient explained as being due to the rubbing on of liniments. The tender area seemed limited to the attachments of the occipito-frontalis. The supraorbital nerve was not tender. There was no discharge from either ear, and the mouth was in an extremely good condition, oral sepsis being put completely out of court. Examination of eye, nose, and throat failed to reveal any condition of disease. She informed me that she had not suffered from sore throat or rashes of any kind—that she had no trouble with her digestion, but that her scalp had been scurfy for some time. All the excretory functions, as far as I could elicit, were normal. Upon explaining to her the importance of a thorough examination, she consented to my finding out whether any vaginal discharge existed or not. I found a muco-purulent discharge present in small quantity in the vagina, and a drop of muco-pus could be squeezed from the urethra. I obtained films, and the gonococcus was found to be present. I diagnosed gonorrhoeal rheumatism affecting the aponeurosis of the occipito-frontalis. I instructed her to empty the lower bowel by means of a saline aperient before coming to see me, and I then injected 25 c.cm. polyvalent serum per rectum, allowing her to rest for half an hour in a recumbent position before proceeding home. I ordered a vaginal douche of 1 in 4,000 zinc permanganate, and gave her grains v of guaiacol carbonate three times a day. The usual directions as to diet and aperients were given. I had intended to repeat the injection of serum, but found this to be unnecessary as the patient made steady progress towards a complete recovery.

L.R.C.P., etc.

THE EXTIRPATION OF CANCER WITH FORMALIN.

I AGREE that the extirpation of cancer with formalin is not a new treatment, and your article reminded me of a case in which I employed it years ago, shortly after the use of the drug became general; and though I did not think there was anything wonderful about it, perhaps a short report may be of interest.

An elderly woman came to me with a small scirrhous tumour of the right breast. The conditions were very favourable for excision, and I urged immediate operation. She went away to think over it, and I did not see her again for about nine months, when she was brought into hospital suffering from profuse haemorrhage proceeding from a sloughing ulcer at the apex of a huge mass of cancer. To check the haemorrhage I plugged the deep pit with wool, and, in the hope of abating the stench, I thought I would try the effect of formalin. I think I used a solution of formalin and water, equal parts. I left the plug in for some days, and, on removing it, I was surprised to find a considerable area quite dry, and of the consistence of cheese, and this I cut away until red showed in the black mass, and I then plugged it again. I continued this treatment for some ten weeks, during which the patient suffered no pain; and, when I judged the whole of the tumour had been destroyed, I left the sloughs to separate, which they did in due course, leaving a clean granulating surface free from any trace of disease. Unfortunately, the patient died not long after of cancerous deposits in various internal organs. I made one mistake. I carried the caustic action of the formalin too deep over the centre of the tumour, with the result that three or four of the ribs were exposed, and, when the sloughs separated, the patient had the unique experience of being able to see under two of her ribs. There were some enlarged glands in the axilla, but under the formalin treatment they shrunk until they could not be felt.

It appeared to me that the difficulties of limiting the destructive action of the formalin were too great to make it generally applicable, and I never repeated the experiment.

Cootesbill, Ireland.

T. H. MOOREHEAD.

Reports

ON

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF THE BRITISH EMPIRE.

CASHEL UNION HOSPITAL.

OBSCURE SPINAL PARALYSIS.

(Under the care of Dr. LAFFAN.)

R. G., steward, aged 51, was admitted on August 29th, 1908.

History.

He stated that backache commenced some time in November, 1907; he described it as straggling and worse at night in bed. It continued until January 21st, 1908, when it got very much worse. In June pain in both hypochondria was added to the back pain, but did not trouble him while he lay still. He described his sensations as if a rope were tied around him tight at times. There was no connexion between this cincture feeling and the pain, as one would come at times without the other. He had been exposed to much cold and wet. He had pneumonia of the left lung about fifteen years ago, and about twenty-five years ago sustained an injury to the elbow-joint, from which some splinters of bone seem to have come away. It was not operated on. The joint remained stiff. He was a temperate man and did not smoke. The back pain was not confined to any particular spot, but seemed to be diffused over the whole back from the ribs down to the ilium. On July 1st, 1908, he complained of a sleepy feeling in the right toes, and about a week afterwards in the left toes. This sleepy feeling continued to ascend until it involved the whole of both lower extremities with the adjacent portions of the abdomen and pelvis. He went to a brother's house on July 24th, and soon after that began to notice that his limbs were not as strong as before.

State on Admission and Course.

He was anaemic, thin, and unhealthy. The facial muscles were unaffected. He complained of extreme backache, and it could be seen readily that he was semi-paralysed in the lower limbs. The weakness of these gradually increased. On September 7th he got retention of urine, and found that after two days in bed he could scarcely put his limbs under him at all. He remained in this condition until September 21st, when severe hypochondriac pain set in, followed by entire loss of motor power. During the progress of the case some slight tremors occurred in the muscles once or twice. He never had headache or ocular symptoms. The lower limbs looked somewhat wasted. The pupils were medium in size and sensitive to light. Speech was normal. The retention of urine continued from September 21st. There was no evidence of a paralysed sphincter ani. Enemata, however, came readily away. His intellect was unaffected. Respiration was 24, pulse 108 to 112, temperature 97.6°. The heart and kidneys were sound. Electric reaction was natural, and there was no ankle clonus. The patellar reflex was normal, as was also tactile sensation. I will not weary your readers by details of treatment, which presented nothing new. He gradually sank and died on September 27th, the mode of death being by way of exhaustion.

The diagnosis in this case must remain obscure in the absence of a *post-mortem* examination. Probably the disease was a malignant tumour pressing on the cord. I would here observe that there is an enormous loss to the public and to science occasioned by popular prejudices against *post-mortem* examinations. I believe such prejudices, however, are not so great or so widespread as they were, and that in consequence it should not be impossible to secure compulsory examinations in all institutions where the inmates receive gratuitous treatment.

THE General Association of Medical Practitioners of Norway, which was founded in 1836, will hold its thirteenth congress at Bergen in August next.

Reports of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

Friday, February 5th, 1909.

W. R. DAWSON, M.D., President, in the Chair.

Irish Recommendations of the Royal Commission on the Feeble-minded.

THE PRESIDENT read a paper entitled "The Irish Recommendations of the Royal Commission on the Care and Control of the Feeble-minded," in which he gave a short account of the chief recommendations.

Mr. LOUIS KELLY, B.L., said he was astonished that such a revolutionary report was so little known and the extent of its recommendations so little appreciated by those who professed to take an interest in the subject. In criticizing the recommendations, he wished to point out that while past and present inspectors of lunatics were exclusively medical men, there was no provision in the law as it stood that these posts should be compulsorily assigned to medical men. In England there were legal inspectors who had done good work, and he objected to the exclusiveness of the recommendations in that respect. The recommendations also proposed to make permanent the present local committees who controlled the asylums in the country. He had no great veneration for a scheme by which so much control and authority was vested in men who had absolutely no training or qualification for the duties imposed on them. Such committees had done and were doing things which no person who was interested in the well-being of the insane could justify. Their very irresponsibility might be taken as an excuse for acts of which he would give some examples collected at random, and in which violence to patients under circumstances which gave no justification for it, and committed by men who were notorious for assault even outside the asylum, was condoned. The President had indicated another weakness in the scheme in regard to the course to be adopted when money was sought to be obtained for building purposes. He objected to the proposed multiplicity of control, which only perpetuated one of the fatal defects of the present lunacy system of administration, in which there were nine bodies which had a certain amount of power and authority. He could not, however, conceal from himself that the report was a marked advance, and its generosity towards Ireland was one of its outstanding characteristics. In the special grant for the provision of necessary accommodation it went further than it did in respect of England or Wales. He hoped the recommendations of the report would become more generally known, and to some extent carried out, and that it would not be pigeon-holed, like the recommendations of the Viceregal Commission on Poor Law in 1891, and others, which proposed the most salutary changes.

Dr. LEFFER said the subject of the care of the feeble-minded and the degenerates of the country was inseparable from Poor Law reform, and the latter would have to come first. In the workhouses, as at present constituted, all the factors that made for degeneracy in the population were being run by State aid. If they reformed the workhouses they would prevent the propagation of degenerates and control the feeble-minded. He was old enough to have given written and verbal evidence before the committee appointed by the Lord Lieutenant of Ireland, the Lunacy Administration, whose report was issued in 1891. The recommendations of that committee were never given effect to, because they ignored the legal difficulties of the subject, and nothing had been done since to alter or amend the Irish Lunacy Laws. The chief difficulty would be in controlling the feeble-minded, who numbered twice as many as the idiots and imbeciles together, and who were capable of doing much more injury to the race than the latter. It would be regrettable if they had to depend for the control of the demented and degenerate on the whim of justices of the peace, one of whom had refused to commit an obvious lunatic who the next day killed a farmer.

Dr. McVITTIE said the question of teachers for the feeble-minded was a central point. He was satisfied that there were many children in whom intelligence developed late,

and that such children, if suitably handled by properly trained teachers, might become useful members of the community. Most of them were ruined in school. Nine out of ten of the teachers under the National Board had nearly all the qualities required to make successful teachers destroyed before they were launched. Their nervous systems were ruined, and their capacity to deal with neurotic or delicate children eradicated. He had examined many such teachers. They were excitable and neurotic, and had been worn and worried by studying a great deal of rubbish for examinations. They would be getting something done if they pressed on the Government the importance of selecting teachers with greater care as regards their physical training. The propagation of degenerates extended beyond the workhouses. There were children in large towns who were reared in unfortunate circumstances as regards health, and if they were to be sent to schools with long hours he was afraid they must have an ever-increasing ratio of feeble-minded people.

Miss BUCHANAN, P.L.G., said that the Viceregal Report, if carried out, would do much to reform the present shocking state of the workhouses in Ireland, and the recommendations of the Royal Commission would deal with the feeble-minded. The Poor Law dealt with destitution, but the feeble-minded and defective need not be destitute in order to be a source of injury to the community. The public did not know that there was only the Stewart Institution to which an imbecile child could be sent, and there were cases constantly coming before her board of guardians in which people not absolutely destitute begged that an imbecile child should be sent to the institution. But because the Stewart Institution had come to be regarded by Catholics as an unsuitable place for their children, such children could not be sent anywhere but to the wards of a workhouse. Even a child sent to an English institution had been brought back because it was found that she was of Catholic parentage. There was no place for sane epileptics except the workhouses. The whole matter called loudly for legislation. The recommendations of Royal Commissions were important, but they were of no use if they were pigeon-holed.

Dr. COLLES said the legal difficulty was illustrated in the recommendation, that the statutory committee of a council, if it did not like the guardianship of a child, could constitute itself the guardian of the child. That had struck the Commissioners as strong, and they provided an appeal to a court of summary jurisdiction, and if any one was dissatisfied with that they could go to the judge of assize. He suggested to the Commission that a better plan would be to vest in the county court judge the power of appointing a guardian, not only of a child, but of a feeble-minded adult, and power to define the powers which the guardian should exercise over his ward. The Commissioners seemed to be inspired by the idea that if they could get a designation that would not hurt people's feelings, opposition would be disarmed, but he thought the associations of the term "mentally defective" would ultimately become as objectionable as the terms "lunatic" and "insanity," which were not originally opprobrious.

The PRESIDENT was of opinion that the ideal method of dealing with the feeble-minded and every other class of mentally defective would be to make the whole thing a national service like the Army Medical Service. He thought, however, it would now be impossible to get rid of the control of the county councils, and that the recommendations provided for their proper subordination to the central authority had the power to stop the grant if everything was not satisfactorily carried out. The number of defectives in workhouses was very large, and the treatment of their mental condition was about as bad as it could be. Many inmates of prisons were drawn from the feeble-minded; almost always they became alcoholic when thrown into criminal associations, and speedily went from bad to worse. The average of previous convictions for Dublin defectives—who constituted 11 per cent. of the inmates of the prisons—was nearly 18. Such facts showed the necessity for interference, and one of the advantages to be derived from any far-reaching system of control would be the placing under detention of women during the child-bearing period, which would diminish and probably extinguish the supply of defectives.

UNITED SERVICES MEDICAL SOCIETY.

Wednesday, December 9th, 1908.

Surgeon-General Sir ALFRED KEOGH, K.C.B., D.G., A.M.S., in the Chair.

Use and Abuse of Alcohol.

FLEET SURGEON ANDREWS read a paper on recent research work on the use and abuse of alcohol. He pointed out that the drink problem was almost coeval with the history of man, and that so far the results obtained by temperance legislation were disappointing. Owing to the unequal powers of resistance possessed by different individuals it was impossible to determine definitely the amount of alcohol which could be taken without harm. At the same time, the steady decrease in the amount of alcohol taken per head per annum pointed to a steady spread of temperance. He pointed out that alcoholism, as the uncontrollable desire to drink to excess, was generally acquired, though sometimes hereditary, and in the former connexion he pointed out the influence of solid customs. Writers were by no means unanimous as to the harmfulness of alcohol; while Starke, amongst others, had pointed out the evils due to the abuse of tea and coffee and the beneficial effects of alcohol as an antidote to theine and caffeine. With regard to the action of alcohol considered as a food, Fleet Surgeon Andrews pointed out that it could only be looked on as such in a strictly limited sense, owing to the impossibility of storing it in the body. Dr. Rivers, however, had stated that alcohol increased muscular work when administered to a person in a state of fatigue, which was somewhat similar in its action to the condition produced by mental fatigue. The vasomotor changes effected by alcohol and the benefits resulting therefrom were discussed, and Bianchi's investigations into the action of alcohol on the heart and circulation were mentioned, as also the effect of alcohol on the blood pressure. The affect of alcohol on bodily organisms was touched on. After some further remarks on alcohol and its connexion with cirrhosis, and in connexion with its effect on the powers of resistance to general infection, Fleet Surgeon Andrews concluded that alcoholic drinks in general and malt liquors in particular were to a certain though limited extent foods; that the effect of alcohol on the individual depended on the nature of the life led, whether sedentary or otherwise, and whether indoor or open air. Alcohol should be looked on as unfavourable to pregnant women and children. It was favourable to muscular work in small amounts, especially when no great mental effort was involved.

Lieutenant-Colonel DAVIES said the total abstainers asserted that it was a poison as to which there could be no doubt; they also denied that it was a food. Food was a substance which could produce heat and energy without deleterious effect. It was not correct to deny that alcohol was a food, although, of course, it did not form tissue. As to the use of alcohol in the army under the conditions of service, they had to consider the conditions of disease, forced exertion, and the special fatigues and exposures of war. As to climate, there was ample evidence from the experience of arctic voyagers and alpine guides and climbers in regard to cold, and from Indian experience as to heat, that alcohol was injurious; as to exertion, the evidence was equally strong.

Sir VICTOR HORSLEY said they had no right to call a substance a food which could not be advantageously utilized in the body. With regard to its being considered a food for the production of work, no one with any knowledge of military experiences would accept any results on the use of alcohol as a food likely to produce muscular energy. The death-rate among moderate drinkers was higher than among abstainers; the incidence of sickness rate was higher than among total abstainers. Under these circumstances he thought they ought to teach that it was a higher national duty to adopt total abstinence than indulge in so-called moderate drinking.

Dr. E. I. SPRINGS said it was striking to notice that whilst methyl, ethyl, and propyl alcohols and others all belonged to the same series and were classed as depressants, no attempts were made to show the beneficial effects of any other members of the group except ordinary alcohol. Although tea and coffee were no doubt frequently abused, he did not think that any one whose work

had taken him among the lower classes of their great towns could pretend for a moment that the harm done by their excessive use was in any way comparable to that done by alcohol.

Sir HAYLOCK CHARLES said contrary opinions were advocated. The drink problem, truly, had been coeval with the history of mankind, and during the stress and strain of the process they termed "civilization," man had sought out many inventions, some helpful, and not a few harmful, for the use made of them. Temperance legislation had been decried, but some endeavour would be made to direct the drink traffic in the road least harmful to the nation.

Fleet Surgeon COLLINGWOOD said that alcoholism was responsible for the diminishing birth-rate; but pointed out that doubtless there were many factors producing such a result.

Dr. COLLINSON said that as to whether alcohol acted as a food or not, he certainly thought that those who did not take drink, or rather were total abstainers, were very much larger eaters than those who partook of alcohol. It would be found that where tea and coffee were taken in excess, instead of alcohol, there was a liability to a certain amount of nervous breakdown.

Sir ALFRED KEOGH thanked Fleet Surgeon Andrews for his very excellent paper. He also said he was sure the thanks of the society were due to Sir Victor Horsley for coming to the meeting. The discussion was a very important one both to the army and navy. He was much struck by the manner Sir Victor Horsley in his speech placed before the meeting the question of alcohol and their relation to the public.

MEDICAL SOCIETY OF LONDON.

Monday, February 22nd, 1909.

CHARLES BARRETT LOCKWOOD, F.R.C.S., President, in the Chair.

Pernicious Anaemia.

MR. L. S. DUDGEON emphasized the fact that the blood in all the cases of pernicious anaemia which were to be referred to in his communication gave a typical blood picture—namely, a diminution of the red cells to about 1,000,000 per c.c.m., a high colour index, various degenerative changes in the red cells, great diminution or absence of rouleaux formation, leucopenia, a relative lymphocytosis, and the presence of nucleated red blood corpuscles—megaloblasts and normoblasts. There was no clinical evidence of any disease apart from pernicious anaemia in any of those cases, and in those instances where an autopsy was performed no cause was found for the severe anaemia. In 9 out of the 11 cases the serum presented a yellowish-green coloration which was quite distinctive. There was no reaction for bile pigment and it failed to give any spectrum. In the remaining cases that coloration of the serum was obscured by the presence of bile pigment. In his experience, apart from pernicious anaemia the reaction did not occur, even in 3 cases where the blood picture was identical with that disease. It had been suggested that anaemia was dependent upon the presence in the serum of a substance or substances which allowed the red cells to be taken up by the phagocytes in the blood. From the observations conducted in the present research there was nothing to support that view when the immune serum and immune red cells were incubated in the presence of normal leucocytes. With regard to pernicious anaemia, however, it was shown, as in the case of the haemolysins and haemagglutinins, that phagocytosis of the immune red cells by normal human leucocytes occurred in the presence of normal serum. Those observations on pernicious anaemia, and similarly in certain other diseases, lent great support to the view that the red cell itself must be reckoned with in observations on immunity. In conclusion, Mr. Dudgeon pointed out that although it was impossible up to the present time to demonstrate many of those most important points concerning the blood immunity of pernicious anaemia, yet it was known that phagocytosis of red blood corpuscles mainly by endothelial cells in the various tissues in that disease, as also haemolysis, was recognized; but how far these changes were directly related to the terminal stages in the disease, and

how far to its actual source, remained to be seen. He did not consider that there was any evidence to show that autoinfection by streptococci and the resulting auto-intoxication was in any way related to the pathology of the disease.

Dr. H. S. FRENCH read a paper on some clinical aspects of pernicious anaemia. In his opinion, slight evening pyrexia was seldom absent in patients affected with pernicious anaemia who were decidedly ill. Pigmentation within the mouth of precisely similar character to that seen in Addison's disease might occur in pernicious anaemia cases treated with arsenic; the spleen was to be felt in about one-third of the cases, and it was really enlarged; nerve symptoms were not at all uncommon in pernicious anaemia; the colour index, though typically higher than 1 when an advanced stage of the disease had been reached, was not always nor continually high, especially during a period of improvement in the patient's condition, when it might be actually low; and pernicious anaemia, as they now knew it, was very possibly only a late and almost incurable stage of a disease which, it was to be hoped, would some day be recognizable early enough to be cured.

ULSTER MEDICAL SOCIETY.—At a meeting held on February 18th, Professor SINCLAIR in the chair, Dr. MAGUIRE read notes of and showed a case of *Acromegaly* in a woman; there was no diminution in the field of vision and no glycosuria, but although the menopause had occurred three years before, the breasts were producing a plentiful supply of milk. Captain STONEY-ARCHER, R.A.M.C., showed a case where the *Clavicle* had been twice fractured with resulting muscular paralysis and anaesthesia of the thumb, side of arm, and hand. Captain Archer had cut down on the part, elevated the depressed bone, inserted an ivory plug, and wire sutured the ends. Anaesthesia rapidly disappeared, and full strength returned; but latterly some pain had been complained of, possibly due to adhesions or callus. Captain Archer also showed a case of *Irritable heart* in a soldier who joined in a route march, and persevered to the end immediately after a post-operation three months' rest. The heart at times was very irregular, at times regular, running up to 160 per minute, and, as shown by sphygmogram, dropping one to three beats, followed by a very forcible upstroke, and further delay. Several members spoke on the case. Dr. CALWELL introduced a discussion on *Ulcer of the stomach*, and the points mentioned were the rise in the curve of age incidence in the female during adolescence, which accounted for the preponderance in the female sex that did not appear from 25 years of age onward, the site of ulcer being nearly limited to those parts which were most constantly bathed in gastric juice during the three ordinary positions of the body. The protection from self-digestion of the mucous membrane was a function of the stomach just as the peristalsis and the opening and closing of the orifice, the secretion of resorcin, pepsin, and hydrochloric acid, and the absorption of fluid and salts; and as these functions were all perverted, even annulled, by various conditions, so it was reasonable to surmise that the function of self-protection might be perverted or annulled by similar conditions. The frequency with which cases of ulcer were associated with migraine, nervous influence, infections, so that corresponding types of ulcer might be formed, lent support to this view. Some remarks on diagnosis and treatment completed the paper. Professor LINDSAY and Dr. DEMPSEY also spoke, and the discussion was adjourned till Thursday, March 4th.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—At a meeting held on February 5th, Dr. WALKER DOWIE, President, in the chair, Mr. JAS. MACLEAN showed a case of a very severe and protracted *Cerebro-spinal meningitis*, with complete recovery, in a female child of 4½ years. The onset was sudden, and the temperature was very variable, frequently dropping from 103° F. to normal in a very short time and as quickly rising again. After seven months' acute illness the temperature fell to subnormal, and did not again become febrile. Meningeal symptoms gradually passed off, and by the eleventh month she was well, but naturally very weak and emaciated. Recovery appeared to have been in great measure due to the large quantities of nourishment she was able to take. A striking feature in the case

was the exudation of a sticky serous fluid from the back of the neck. Dr. KERR LOVE described a case of *Perissinus abscess*, with mural thrombus, in the sinus, basal meningitis, and tuberculous tumours in the pons, cerebellum, and cerebrum. He considered there was a danger of the aurist too often considering tuberculous ear disease to be primary or secondary only to disease of the temporal bone, whereas many were hopeless cases of general infection. Such theories led to aggressive surgery, and perhaps to the opening of the cranial cavity in hopeless cases. Taking the view that the affection in the temporal bone was carried from a distance by the blood stream, the primary lesion being in the thorax or abdomen, more conservative treatment was called for, and one would be slow to open the cranial cavity unless localizing symptoms of a curable condition declared themselves. Dr. KENNEDY showed the pathological specimens. Dr. HENRY RUTHERFORD showed a girl, aged 8, the subject of *Ossseous ankylosis of the jaw after otitis*. The condyle and neck were excised and she could now open the mouth well, but the teeth, especially the incisors, were not accurately apposed. He also discussed some cases of contusion injuries of the abdomen, illustrating how conflicting symptoms might be. He thought that in cases of doubt it was much better to operate. A specimen of *Rupture of the colon by bursting (éclatement)* was also shown.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—At a meeting held on January 21st, Dr. RENNET, President, in the chair, a discussion on *Anaesthesia* was introduced by Professors CASH and MACWILLIAM and Dr. DALGARNO, Senior Anaesthetist to the Royal Infirmary. Professor Cash stated that chloroform was intrinsically toxic in its effect, that primary heart failure might occur, though usually respiration was first affected. There was a fall in the blood pressure with chloroform before the reflexes were gone, which was not the case with ether. Chloroform reduced the oxygen-carrying power of the blood, and narrowed the coronary vessels; ether dilated these. In chloroform anaesthesia there was a narrow margin between anaesthesia and injury to the organism. The heart toxicity of chloroform was many times greater than that of ether. In imperfect anaesthesia there was reflex danger with chloroform, not with ether. Any danger with ether was readily removed by careful administration and proper temperature, while no amount of care would entirely avert danger with chloroform in certain cases. In concluding, he expressed the opinion that unless there was strong reason to the contrary, ether should be chosen as the routine anaesthetic. Professor MacWilliam confirmed certain of the above opinions, and referred to the microscopic changes which took place in the brain cells after chloroform, the body of the cell becoming attenuated, though they showed great and rapid powers of recovery even after deep and prolonged anaesthesia. Chloroform relaxed the muscles of the heart and arteries, and while heart, respiration, and arteries were all acted on, the heart was the chief factor in danger. Too strong a vapour exerted an inhibitory action through the vagus which might kill immediately. The important point was not the percentage of chloroform in the air taken into the chest, but the steady intake into the circulation, which varied according to the rapidity and depth of breathing. In his opinion, chloroform should not be given as a routine anaesthetic without considering whether ether or local anaesthesia might not meet the case. Dr. DALGARNO dealt with the practical application and administration of anaesthetics, pointing out the necessity of careful preliminary examination and preparation of patient, and detailed the changes in technique necessary for the anaesthetizing of alcoholic, timorous, fat patients, etc. Previous starvation and purgation might be overdone. The preliminary administration of drugs—strychnine, saline infusion, morphine and atropine, sparteine sulphate, etc.—were dealt with. Various forms of apparatus were exhibited and discussed, and various anaesthetic sequences were considered, and he gave statistics from the records of the Aberdeen Royal Infirmary for three years, during which time 4 deaths occurred out of some 6,000 cases, all of which took place in the early stage of administration of chloroform and in bad cases, 2 of them emergency operations. Mr. SCOTT RIDDELL then dealt in a very complete manner with spinal analgesia, sketching

the history of this method, and detailing the advantages and disadvantages which it had. The discussion was adjourned till the next meeting.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—At a meeting held on February 5th, Dr. W. H. CRETHERM in the chair, Dr. MACGREGOR YOUNG opened a discussion on *Anaesthetics*. In comparing the relative safety of ether to chloroform he said that the British Medical Association Committee had found that chloroform was seven times more dangerous to life than ether; but, in his opinion, if its finding had been that chloroform was seventy times more dangerous, he would still have thought the proportion understated. Ether as an anaesthetic vapour administered with reasonable care was not dangerous at all, whereas chloroform even in skilled hands might be attended by fatal results, and he did not think any apparatus had brought its administration within the limits of absolute safety. With regard to the after-effects with which ether was credited in the way of bronchitis, bronchopneumonia, etc., this was so much a question of personal experience as to make general conclusions of small value. For his part, the more he gave of ether the less was he inclined to blame the anaesthetic and the more its faulty administration, the absence of warmth during the operation, in the theatre, the corridor, the ward or bedroom, and the after-care of the patient in the way of inhalation, posture, etc. As regards ethyl chloride, the eccentricities and even fatalities of this anaesthetic might be due to a failure to appreciate the enormous difference that the warmth or coldness of the apparatus made in so volatile a drug. The status lymphaticus was discussed: acid intoxication as a cause of death after chloroform was not always recognized. He had seen one death lately from this cause in an adult. The patient had had anorexia for weeks, and was starved in consequence, from an unrecognized tuberculous peritonitis. The strangulation of a ventral hernia necessitated urgent operation. Chloroform was given, with the result stated. He had tested the urine in 40 cases for acetone, and found it in 1 before and 5 after operation. In none were there any untoward effects. Ether was the anaesthetic given. Mr. PAINCE TEALE supported Dr. Macgregor Young's conclusions as to the safety of ether compared with chloroform, and drew attention to the increasing employment of the former anaesthetic. He also outlined the history of the introduction of ether as an anaesthetic. Dr. J. B. HELLIER said he thought that bronchitis and pulmonary complications generally were much more frequent after the administration of ether than after chloroform had been given, and that deaths from these causes were not infrequent. In estimating the safety of an anaesthetic, one had therefore to take into consideration not only deaths during the administration, but occurring later owing to its secondary effects. Mr. H. LITTLEWOOD showed (1) a *Meckel's diverticulum* removed from the hernial sac of a child 3 months old, and (2) a *Stone removed from a horse-shoe kidney*. Dr. A. G. BARES showed a case of *Gonorrhoeal arthritis treated with vaccine*. Dr. ALEX. D. SHARPE showed a case of *Syphilitic affection of the nose and pharynx*, and advanced *Tuberculous disease of the larynx*. Mr. W. THOMPSON showed a *Large intestine showing two malignant growths*, one of which perforated after ileo-sigmoidostomy. Mr. J. F. DORSON showed an *Omental band causing attacks of intestinal obstruction simulating appendicitis*. Dr. WARDROP GRIFFITH showed a case of *Mitral stenosis with phthisis*. Cases and specimens were also shown by Dr. D. SANDERSON LONG, Mr. J. BASIL HALL, Dr. E. O. CROFT, Mr. B. G. A. MOYNIHAN, Dr. J. B. HELLIER, Dr. C. OLDFIELD, and Mr. SECKER WALKER.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—At a meeting held on February 17th, Dr. J. MACKIE in the chair, Dr. A. STANLEY GREEN (Lincoln) read a short paper on *The uses of Bier's hyperaemia in general practice*. This was Nature's method of bringing up reinforcements and was valuable both for the relief of pain and also in septic cases the need for repeated fomentations was done away with, while much smaller incisions would suffice where these were necessary. Passive or venous hyperaemia was produced by suction glasses or rubber bandages as shown, and instances were given of the value of such treatment

in septic wounds of the limbs and fingers, of the scalp facial erysipelas, chronic ulcer of the leg, orchitis, gonorrhoeal and tuberculous arthritis, mumps, mastitis, axillary abscess, boils, and carbuncle. Where possible it was also advisable to prepare a vaccine from the patient's own pus, and utilize this in the treatment. The paper was discussed by the CHAIRMAN, Drs. W. T. ROWE, R. B. PURVES (Lincoln), W. HUNTER, and R. WOOD (Ikeston), and Dr. GREEN replied. Dr. W. T. ROWE read a short paper on *Indigestion in children beyond the age of infancy*, in which he traced the various symptoms to which indigestion might give rise in children, and after alluding to the marked idiosyncrasy exhibited by some children to certain articles such as eggs or porridge, criticized the overuse of certain foods, such as bread and butter, potato, porridge, brown bread, fruit, salt meat, and root vegetables. He also made suggestions as to treatment and alterations in a faulty diet. The paper was discussed by the CHAIRMAN, Drs. F. H. JACOB, A. S. GREEN (Lincoln), R. M. HAMILTON (Annesley), J. S. BOLTON, A. FULTON, W. HUNTER, A. J. SHARP, and S. E. GILL, and Dr. W. T. ROWE replied. Dr. C. H. ALLEN showed a case of *Marked hypertrophy of the penis*, apparently due to lymphatic obstruction, in a collier aged 44, who had received a severe blow in the groin six months previously. The condition had been materially relieved by circumcision, but at one time the penis had measured 8 in. in length and 8 in. in circumference. Dr. THOMSON HENDERSON showed sections of an *Eye in which a magnetic fragment of steel had been embedded more than four years*, also other specimens showing pigmented and unpigmented sarcoma of the choroid. Dr. R. B. PURVES (Lincoln) showed a *Fibro-sarcomatous tumour*, weighing 6½ lb., in the testicle, removed from a man aged 70, two years ago without recurrence; an *Appendix attached by two shroud-like adhesions to the posterior wall of the bladder in a man*, and prior to removal causing micturition at regular and definite intervals; also *Fullopian tubes, the seat of chronic inflammation*, in a girl aged 20, and removed on account of fistulous pyuria occurring through the posterior wall of the bladder, and leaving a urinary fistula after operation.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—

A clinical meeting was held at the Medical Society's Rooms on Thursday, February 11th, Mr. E. NETTLESHIP in the chair. Mr. BISHOP HARMAN showed *Models on an economical plan for the Diaphragm test and a Substitute for smoking* for the use of patients suffering from tobacco amblyopia who felt the loss of their tobacco. The latter consisted of quassia made up in the form of chewing-gum, and the idea was suggested to him by the remark of a night watchman with tobacco amblyopia, who had to sit by a fire all night and did not know how to employ his time if he did not smoke. Dr. A. LEVY showed a case of *Obstruction of the cilio-retinal artery*. The vessels were sclerosed, and that was the only evidence of arterial disease, the viscera being sound. Mr. CUNNINGHAM showed a case of *Aniridia* and gave the family history of the condition. Mr. NETTLESHIP brought three drawings illustrating *Hæmorrhages, believed to be choroidal*, following a blow on the eyebrow; also choroiditis behind the retinal veins. Mr. HANCOCK showed a case of *Pituitary neoplasm with ocular symptoms* in a child. The physique of the child seemed to suggest that it was an early case of acromegaly, and skiagrams showed an abnormal appearance in the pituitary region. Mr. MACNAB called his attention to a paper on the subject by Uthoff at the Heidelberg Congress. Dr. MACKENZIE DAVIDSON exhibited the skiagrams of the case, showing the small abnormal opacity in the region of the pituitary body in front of the sella turcica. He said he had never seen an appearance of that nature before. Mr. LESLIE PATON said he had seen a case of a similar nature at intervals in the last six years. The boy developed intense optic atrophy in both eyes, evidently due to pressure on the chiasma, and the sequel was that he was now in an asylum. Mr. MACNAB gave a synopsis of the paper by Uthoff to which allusion had been made. Mr. FISHER questioned whether the skiagram enabled one to say that the bone cavity containing the sella turcica was enlarged. Mr. E. W. BREWERTON showed a case of *Cyst of the iris* which at first had the appearance of sarcoma. Mr. RAYNER D.

BATTEN showed two cases of *Hereditary retinitis*. He believed it was a retinitis with secondary atrophy rather than an actual atrophy.

HARVEIAN SOCIETY OF LONDON.—At a clinical meeting held at St. Mary's Hospital on January 28th, Dr. WILLIAM HILL demonstrated *Direct vision laryngoscopy and Tracheobronchoscopy*, using Brining's or Chevalier Jackson's instruments. He showed: (1) *Growth on right vocal cord*; (2) *Pachydermia of cords*; (3) *Tuberculous growths*; (4) *Tuberculous laryngitis*, where the ulcerations had healed under daily direct vision treatment in hospital; (5) *Subacute laryngitis*; (6) *Chronic laryngitis*. He also demonstrated the *Bifurcation of the trachea*. After cocaineization of the larynx a tracheoscope was passed through the vocal cords during inspiration to a distance of 3 in. After further cocaineization, Brining's extension bronchoscopic tube was passed through the tracheal tube to the bifurcation. No coughing occurred in any of these cases, showing the efficiency of Mr. Harrison's method of cocaineization. Dr. Hill also showed the apparatus used in *Oesophagoscopy*, and related a case in which he had used it. He showed Chevalier Jackson's *Gastroscope*, together with the laryngeal and tracheal instruments of Kirstein and Killian, which led up to the perfected instruments of Brining and Jackson. Mr. CECIL GRAHAM exhibited by direct laryngoscopy the condition of a *Tuberculous patient from whom an interarytenoid tubercle had been removed under chloroform* by the aid of Brining's laryngoscope. Mr. FITZMAURICE KELLY showed a case of *Endothelioma of the tonsil with enlargement of the cervical glands*, and also a case of *Osteo-arthritis of the left metatarsophalangeal joint associated with cystitis*. Dr. WILCOX showed a case of *Collapsed lung with secondary fibrosis* in a child. He discussed the possibility of congenital bronchiectasis and fibrosis following phthisis. Mr. LAMING EVANS showed a case of *Congenital dislocation of the left hip of the supra-cotyloid variety* in a girl of 7. There was a complete absence of lordosis. Trendelenburg's sign was present.

Rebiefus.

DIETETICS.

WE may congratulate Dr. G. A. SUTHERLAND on the successful accomplishment of the well-planned *System of Dietetics* which, under his editorship, has been added to the series of Oxford Medical Publications.¹ He has secured the co-operation of a distinguished body of collaborators, who have amply justified his choice. The volume opens with an introductory chapter by Sir Lauder Brunton, which contains practically all that such an introduction should include, but the student would have been helped by a short bibliography, giving references to the chief works which have influenced modern thought on this subject.

Dr. Harry Campbell is interesting and philosophical on the evolution of diet, following on the lines traced by Malthus and Darwin. He imagines the simian ancestors of mankind as living on fruits and roots, insects, vermin, birds, small reptiles, frogs, eggs and small mammals, just as some monkeys do now, and he describes the hominid as gradually acquiring greater facility in killing other animals for food, and hence becoming more and more carnivorous. He represents early man, when he had arrived at the stage at which he became entitled to that name, as living by hunting, mainly carnivorous in his food, and not reverting to vegetables for a considerable portion of his diet until after the development of the art of cookery; but before the possession of vessels in which the process of boiling could be adequately performed he was unable to avail himself of the great store of starch which Nature conceals under hard envelopes, and its full development was not until agriculture had multiplied enormously the supply of the most important kinds of starchy food. This process has gone on until, in our own time, the proportion of vegetable food in the diet of man is greater than

¹ *A System of Diet and Dietetics*. Edited by G. A. Sutherland, M.D., F.R.C.P. Oxford Medical Publications. London: H. Frowde (Oxford University Press), and Hodder and Stoughton, 1908. (Roy. 8vo, pp. 906. 30s.)

it has ever been since he bore that title. Dr. Campbell does not consider this a matter for congratulation. He shares the view that the excess of carbohydrate food eaten now, in what he calls, perhaps not very politely, the "age of pap," is largely the cause of the decay of teeth, especially as it is presented in a form that demands so little mastication.

Dr. E. I. Spriggs has written admirably on the physiology of digestion; in fact, too much praise cannot be given to the care he has taken to place before the reader an account of the present state of knowledge, so that while not disguising the gaps that exist, the story of the digestion and absorption of food in man is made intelligible. He might have mentioned the evidence tending to prove that the food lies in layers in the stomach, that last swallowed occupying the central position, so that it does not come at once in contact with the gastric juice, as this arrangement explains how it is salivary digestion may continue for a considerable time after food has reached the stomach, and justifies the practice of taking pudding after meat, which, without this explanation, seems to be irrational, since a quantity of carbohydrate food is introduced into a stomach when digestion is in full activity and much acid gastric juice present. The utility of Dr. Spriggs's article is greatly increased by the inclusion of the valuable tables of the composition and heat-value of different articles of food compiled from Atwater and Bryant. The arguments on both sides of the controversy respecting the protein requirements of the body are stated temperately, but scarcely do justice to Chittenden's contention that we cannot rely upon "preference" as a safe ground for dietetics; the more recent experiments made by the same observer on dogs are not given, although reference is made to those of Rosenheim and Munk, which are adverse; in fact, he hardly appreciates sufficiently Chittenden's arguments and facts as set forth in his latest book (*The Nutrition of Man*, 1907), where some of the objections raised are dealt with.

Dr. E. Cantley describes the various dietetic cures in vogue, and has hardly a good word to say for one of them. Dr. Spriggs is an advocate for the common experience of mankind as against Chittenden, but Dr. Cantley uses Chittenden against the faddists. He draws a gloomy picture of the economic effects of vegetarianism, but we doubt if he is justified in thinking that if it were pushed to its logical conclusion it would not pay to keep sheep for wool or cows for milk or fowls for eggs. Long before there was any prospect of the mutton of New Zealand and Australia being available for the food of Europe, when carcasses were boiled down for tallow, it paid to keep sheep at the Antipodes, while in India at the present day cows are kept for milk and fowls for eggs. The chapter on proprietary foods, also by Dr. Cantley, contains an instructive table giving information respecting the composition and nutritive value of most of these articles. Dr. F. D. Boyd writes on artificial feeding, a subject upon which he has already done good work.

Dr. Harry Campbell, who writes on alcohol, accepts the views of Dr. Archdall Reid that races of mankind become gradually immune to the "charm" of alcohol, and that drunkenness is a sign of recent civilization, or at least of recent access to the free use of alcoholic drinks. While not advocating total abstinence, he is justified in pointing out that large numbers of people take far too liberal a view of what they are pleased to call moderate drinking.

The subject of feeding in fevers has been entrusted to Dr. Claud Ker, who deals somewhat vaguely with the diet in enteric fever; in discussing the alleged advantages and obvious objections to the use of solid food he has left the question more open than seems prudent. It is quite true that many mild cases do well on semi-solid food, but some who have given it a trial for some years have abandoned it owing to the occurrence of accidents from time to time which were probably due to it and which might have been avoided by following a more cautious regimen.

Drs. Noel Bardwell and Chapman, in the section on diet in tuberculosis, repeat the substance of their excellent and well-known monograph on the subject. Their opinion that very high feeding often results in the arrest of the tuberculous disease should be noted. Great praise is due to these gentlemen for the pains they have taken to study the cost of diets and to show that cheapness is not inconsistent with efficiency.

The chapter on the diet of gout and rheumatism is by Dr. A. P. Luff, who advocates for the gouty the adoption of Chittenden's dietetic principles, but repudiates the notion that meat is a poison, and will have nothing to do with "purin-free" diets. He makes some common-sense remarks upon the popular prejudice against potatoes and strawberries in gout and on the insufficient consumption of fluids by women. The article on the diet of diabetes by Dr. Rose Bradford is disappointing, as it fails to say anything as to the need for making the diet rules quantitative as well as qualitative, nor does it point out that a satisfactory diabetic diet must contain a sufficient number of heat units. Considering the importance of the subject, the article is too short, as may be seen if we compare the ten pages devoted to it with the fifty allowed to the diet of tuberculosis.

Dr. Cantley has written a good article on the treatment of obesity, giving a clear account of the principal dietetic systems, but he does not mention the importance of meat as an appetite producer; however, his general principle of an all-round reduction in the diet is quite sound. We note that he gives an abstract of the article on the different proprietary remedies for obesity which was published in this JOURNAL. Diet in arteriosclerosis is dealt with by Dr. Campbell, who says all that in the present state of our knowledge can be safely affirmed respecting it, and says it very well.

The important chapter on the dietetic treatment of stomach and intestinal diseases is written by Dr. H. P. Hawkins. He describes methods of examination after test meals, but it is doubtful whether it is desirable to reduce the quantity of fluid given with an Ewald test breakfast from half a litre to half a pint as the quantity of contents obtainable is often rather scanty. He prefers an enema containing 1 oz. of dextrose dissolved in 10 to 15 oz. of normal saline solution to the ordinary nutrient enemata used for rectal feeding. He discusses the diet of hyperacidity very sensibly, and his conclusions are, we believe, in accordance with general clinical experience. He does not seem as certain as he might be that surgical interference for gastropnoia is worse than useless, but on the other hand he perhaps exaggerates the incurability of extreme cases, as we know of one case in which in 1901 the great curvature reached the pubes, yet the lady is now and has been for some years perfectly well. We cannot help regretting that Dr. Hawkins did not give such diets as he would prescribe instead of copying those of German authors, which are not always adapted to English palates or composed of articles in common use in this country. The theory that flatulence may be accounted for by exhalation of CO₂ from the veins of the stomach is, as Soupault called it, a pure hypothesis; deficient mastication, whether from defective teeth or otherwise, is by far the most common cause of this affection.

Dr. Hale White has only a limited subject to deal with in jaundice and other affections of the liver, but he has said what is necessary very well. We may refer in passing to his experience with the subcutaneous injection of oil as proving it to be a practicable means of aiding the nutrition of the body.

Dr. Sutherland writes on the dietetics of diseases of the lungs other than tuberculosis. It would not have been out of place to have mentioned the remarkable relief occasionally given by an emetic in attacks of asthma, and in the indication for alcohol in pneumonia he has not mentioned the collapse that sometimes occurs after the crisis. It would have been well to give more exact directions than that alcohol should be given "at regular intervals," and it is exceedingly doubtful whether the chronic alcoholic when suffering from pneumonia is benefited by the administration of alcohol; on the contrary, he is often intolerant of its effects, and it has to be replaced by digitalin and caffeine. Dr. Hadley writes on the dietetics of heart disease, a subject upon which there is not much to be said, but what there is may be found here.

Dr. Rose Bradford deals with the diet in urinary and renal diseases on generally approved lines, but he does not mention the views of Klemperer on the importance of excluding lime and foods containing lime, while giving preference to those containing magnesium bases, in the treatment of oxaluria.

Dr. James Taylor, who discusses the diet in nervous

diseases, does not mention migraine, and, curiously enough, neither migraine nor headache appears in the index. Graves's disease is dealt with in three of the chapters—namely, in those on nervous diseases, on heart disease, and on blood diseases.

Dr. Colcott Fox, who has contributed the chapter on skin diseases, has made less of it than might have been expected. Under the heading, "Diet in Old Age," Dr. Campbell sets out what is known of the matter; while Dr. Sutherland's chapter on diet in the diseases of infants and children of necessity to some extent repeats what has been said in preceding chapters, but is sensible and sound.

The last chapter is that by Sir Patrick Manson on diet in the diseases of hot climates, a subject with which he deals briefly, but with a knowledge founded on great experience.

We have found these essays eminently readable, and in our opinion the book is one which not only deserves to be read and appreciated widely, but to be kept for reference on the shelves of every practitioner.

THE DISEASES OF AGED PERSONS.

The old adage that a man is only as old as his vessels has always been held to be a sufficient explanation of premature degeneration of elderly folk, but a wider study of the physiological and pathological changes as age advances, such as is presented in the comprehensive treatise recently put forth by Professor RAUZIER, of the Montpellier School of Medicine, opens up many interesting problems that have been somewhat neglected in the general textbooks.

That the author has devoted many years of careful investigation to his subject is proved by the introductory chapter contributed by Dr. Grasset, who incidentally criticizes the views of Metchnikoff with respect to the immortality of certain tissues, such as the cell which divides into two living cells, leaving no dead cell behind it, and maintains the thesis that every living being dies at its appointed time. Death is a natural process, but old age is a disease which can to a certain extent be retarded, and, if it were possible to safeguard the body from the wear and tear of mental and bodily ills, there is no reason why the patriarchal term of years should not be attained.

Dr. Rauzier's book is large, and has doubtless been in preparation for a long time. It is obviously the work of a physician who brings to bear upon his subject the teachings of a wide clinical experience and a close study of the writings of previous observers. The modifications of disease as occurring in the persons of patients over 60 years of age is the real text of the work, and, as a preliminary, the author examines closely into the changes which must be regarded as normal to the gradual oncoming of senility. Foremost among these are those affecting the circulatory system. Great stress is laid upon the importance of recognition of the universal affection of all the blood vessels, which has been described by Boy-Tessier as "arterio-xerosis." This is held to be a natural process, but somewhat unequally distributed. It is regarded as distinct from what is generally known as "arterio-sclerosis" in the fact that it is common to all vessels, both arterial and venous, and that it is not subject to the fatty or calcareous degeneration which constitutes atheroma. Such a process of slow hardening of vessels must of necessity influence the course of diseased conditions when they occur, and throughout the consideration of the diseases of the various systems this underlying factor has always to be reckoned with. As in development the vessels are the earliest to come to perfection and the brain the latest among vital organs, so in old age the brain may remain unaffected while the general vascular system has undergone profound change. The powers of the mind are often retained in almost pristine fullness long after the body has become enfeebled by the natural onset of decline. Gradual failure of function, whether of the muscles or of the internal organs, is the first evidence of senility. The old man can neither move about nor eat and drink with the same impunity as before, but within the limits of his powers his functions are not materially disturbed, they are only diminished.

The first part of Rauzier's book is devoted to the consideration of this normal decline, and the later parts to close examination of the diseases of the various systems and the modifications which they present when occurring in old people. In so comprehensive a treatise there must be a certain amount of overlapping, and the book as a work of reference would gain by compression, more especially in the discussion of those forms of disease which are chronic and usually prevent the attainment of old age. A good account is given of the blood changes in late life and of the conditions of the heart, which, like the blood vessels, undergoes certain changes which render it less able to resist the extra strain thrown upon it by over-exertion or by disease of other organs. The respiratory and digestive systems present many interesting modifications, and the proneness of the alimentary canal to be affected by cancer in any part of its course in the persons of the aged is fully discussed and the arguments for and against operative treatment carefully weighed by comparison of results obtained in many clinics.

Affections of the kidney are described at somewhat unnecessary length. The subject of renal insufficiency from any cause rarely attains to long life.

The diseases of the nervous system and of the skin are fully discussed, the latter being dealt with by Dr. Vedel, Professor of Dermatology at Montpellier.

So comprehensive a work on a subject which has rarely been studied collectively from the clinical point of view should be welcome to all schools of medicine. While many of the diseases of old age are apparently in their course the same as in the adult, there must always be borne in mind the structural changes incidental to advancing years, which are implied by the term "arterio-xerosis," already referred to. A gradual shrinkage of cell tissue, with an equally gradual development of connective tissue, must be assumed to be continually at work as a normal process, while the thousand and one causes for vascular degeneration in individual organs or areas may be influencing the vascular supply at the same time. Thus the state of his vessels does, indeed, influence the age of the patient and the manner in which it modifies the course of disease is well shown in Dr. Rauzier's book.

THE SOUL OF SPAIN.

A REALLY good book on a foreign country is by no means a common thing. Many people, after a hasty tour of a few weeks, during which they visit only the big cities and live at hotels, think themselves capable of writing exhaustively on the manners and customs of a people; but books of travel written in this fashion are worse than useless—they are misleading. A foreigner can know little or nothing of the character of a people with whom he has had no actual intercourse, of whose ways of thought, religion, and social life he is completely ignorant. At every turn he comes upon something which he does not understand, which, ten to one, he misunderstands and misjudges; and in this way all sorts of mistakes concerning other nations arise, and in some cases do untold harm. This has been particularly the case with regard to Spain, a land of which most Englishmen know little and understand less. This reproach cannot be justly brought against Mr. HAVELOCK ELLIS. In his charming study, *The Soul of Spain*,¹ which is not a book of travels in the ordinary sense of the word, he has striven to bring before us the real Spaniard with all his characteristics, as they are shown in Spanish art and literature, and he has been entirely successful. He has written with such insight and sympathy—one might almost say with such love—that it is impossible to read his book without understanding Spain better and realizing a little what a great nation she still is.

In the preface Mr. Havelock Ellis refers to his work as "inadequate and superficial," but there is no trace of superficiality throughout the book. He has returned to Spain again and again, studied her history, art and literature, and learnt to know her people from within, till he can look on life with the eyes of a Spaniard; and the result is a strikingly vivid portrait that few Englishmen could have drawn. Not many of our countrymen, for example, could understand the Spaniard's attitude towards religion so

¹ *Traité des Maladies des Vieillards*. [Treatise on the Diseases of Aged Persons.] By Dr. G. RAUZIER, Professor of Pathology and General Therapeutics, Montpellier, with a Preface by Professor Grasset. Paris: J. B. Baillière et Fils. 1909. (Demy 8vo, pp. 705. Fr. 12.)

² *The Soul of Spain*. By Havelock Ellis. London: A. Constable and Co. 1903. (Mel. 8vo, pp. 430. 7s. 6d.)

thoroughly as the man who can write about their behaviour in church in the following terms :

We realize how far we are from the present when we enter a Spanish church. The ecstatic attitude of devotion which the worshippers sometimes fall into without thought of any observer is equally unlike the elegant grace of the French worshipper or the rigid decorum of the English, while perhaps, if it is a great festival, groups of women cluster on the ground with their fans at the base of the piers, and the children quietly play about in corners with unchecked and innocent freedom. Nor are the dogs and cats less free than the children: at Tudela I have even seen a dog curled up in the most comfortable chair by the high altar, probably left in charge of the church, for he raised his head in a watchful manner when the stranger entered; and in Gerona Cathedral there was a cat who would stroll about in front of the *capilla mayor* during the progress of Mass, receiving the caresses of the passers-by. It would be a serious mistake to see here any indifference to religion; on the contrary, this easy familiarity with sacred things is simply the attitude of those who in Wordsworth's phrase "lie in Abraham's bosom all the year," and do not, as often among ourselves, enter a church once a week to prove how severely respectable, for the example of others, they can on occasion show themselves to be.

This "easy familiarity with sacred things" is an essential part of the Spaniard's character; his religion permeates his whole life. In another passage Mr. Havelock Ellis, in speaking of the anticlerical movement and the growth of scepticism in Spain, says:

We cannot well imagine the religious element in the Spanish people dying out. It is too deeply ingrained in the very fibre of the race. If Catholicism had no existence in Spain one feels that the Spaniards would invent it. Mysticism, even monasticism, is part of their very temperament, a temperament at once so ardent and sensuous, so ascetic and unflinching.

These lines describe the Spanish character derived, according to the author, partly from race and partly from the influences of climate. The Spaniard is descended from African stock, says Mr. Havelock Ellis,

and remains to-day, in the best sense of the word, a savage. His childlike simplicity and intensity of feeling, his hardness and austerity combined with disdain for the superfluous, his love of idleness tempered by the aptitude for violent action, his indifference to persons and interests outside the circle of his own life—these characteristics and the like, which have always marked the Spaniard, mark also the savage.

The climate of Spain has further accentuated these characteristics, with the result that no nation, perhaps, has been so persistently misunderstood as the Spanish. The charge of cruelty, for instance, which is so often made against them is no more merited by them than by any other nation. It is true that the Spaniard is indifferent to pain, but this does not prevent his being capable of deep tenderness and indulgence. Strange as it may sound, many of the Spanish casuists have been famous for their indulgent views in theology, and even the Inquisition is now recognized to have been less cruel than many other religious persecuting bodies. Mr. Havelock Ellis cites Valera as his authority for saying that the town of Salem alone

was responsible for more torture in the name of religion than can be put to the account of the Holy Office from California to the Straits of Magellan.

Those who accuse Spaniards of cruelty would do well to remember that it was in Spain that the first hospital for the insane was founded six hundred years ago, and that the treatment of the inmates was infinitely more enlightened than in our own asylums two or three centuries later. The bull-fight is another form of Spanish cruelty which the Englishman is fond of decriing; but, as Mr. Havelock Ellis justly remarks:

In Spain itself only a section of the public cares for bull-fights; very many Spaniards of all classes do not go and do not like it; the part of religion in the native progress are equally opposed to it. Certainly it is the national sport of Spain, just as horse racing and betting constitute the national sport of England. In both cases alike we must not identify the whole nation with the national sport. Apart from its repulsive elements—which are as objectionable to many Spaniards as to the stranger—the bull-fight is a fascinating exhibition of skill; and, since the contest with the bull is very rapid and the animal's death swift and certain, it must be said that if sport is to be defended at all, this kind of sport compares favourably with fox hunting or pheasant shooting. The element of risk also, the fact that the would-be slayer may himself be slain, adds an element of dignity which is wanting in nearly every other form of European sport.

If our insular ideas concerning Spanish men are revolutionized by Mr. Havelock Ellis, this is still more the case

with regard to Spanish women, whom he is inclined to regard on the whole as superior to their countrymen. The languorous, passionate beauties so often depicted in novels, plays, and pictures are not typically Spanish. On the contrary, the typical Spanish woman is specially marked by sweetness and strength; the ideal Spanish woman is at once strong, independent, self contained, and at the same time wholesomely gracious and gentle. She is, as Valera says, "angelic but robust." This last-named quality is very marked; the average Spanish woman is not only strong, she possesses a vast fund of energy. Mr. Havelock Ellis says:

Not long since I spent a Sunday in the old Castilian city of Palencia, and watched how the women—stout and matronly as well as young women—amused themselves at a game between bowls and ninepins, casting the large heavy balls along the grass with unwearying satisfaction during the whole of a long afternoon in the most businesslike and yet gleeful manner, while a few children stood looking on at their elders. I have never seen English women of the people, or indeed the women of any other land, playing at anything so vigorously healthy and innocent for the sheer joy of muscular exertion, and a race whose mothers have so much wholesome energy to spare can scarcely be very exhausted or decadent.

These last few words are significant, for they express the author's opinion of the state of modern Spain. All her modern writers are pessimistic regarding her future, but Mr. Havelock Ellis does not agree with them. The real root of the evil, he holds, lies in the Spaniard's belief that the life of his country is finished, that the race is decadent, unable to carry on the traditions of their ancestors. Let them but once realize that this is not the case, that the bulk of the Spanish nation is as sound and strong as ever, and their problem will be solved. The concluding words of this interesting and instructive book are full of hope and encouragement, and Mr. Havelock Ellis leaves us with the conviction that there is a future, and that a glorious one, for Spain.

FORENSIC MEDICINE.

WHAT are the relative values of the precipitin test and the "deviation of the complement" test for the forensic differentiation of human from animal blood? This is the question which is discussed by several eminent German pathologists in a pamphlet published recently in Berlin.¹ From his high position as an authority on forensic medicine Professor Uhlenhuth's opinion is naturally of great importance. In his view, the "deviation of the complement" method, originated by Bordet and Gengou² and adopted by Neisser and Sachs, is of great service in scientific laboratory work where pure albuminous solutions are under investigation. But he attaches less value to it in forensic practice, where we have to deal with traces of blood subjected to all sorts of contaminations. Fallacies arising from many of these complications may be eliminated by special care and the employment of control experiments, but nevertheless difficulties arise from the fact that the "deviation" method is so sensitive that it gives positive results with sweat, mucus, nasal secretion, saliva, etc., and hence may be misleading. These difficulties, he maintains, are not encountered in the precipitin method as employed by him. He therefore considers that it is not permissible in forensic practice to regard a positive result given by the Neisser-Sachs method as overruling a negative outcome of the precipitin test. It is, however, urged by some of the contributors, who regard the "deviation" test as a useful adjunct to the precipitin test even in forensic medicine, that a negative result obtained by the former and more delicate test would, when found, be of service in strengthening the assumption that the presence of the particular blood under consideration could be excluded.

The little book of 128 pages upon toxicology, by F. A. ROSSMÄSSLER,³ is wonderfully comprehensive considering its size, and affords an excellent, though rather superficial, summary of the chief facts connected with a large number of poisons. The author deals with all the important, and with a comparatively large number

¹ Nachprüfung des von Neisser und Sachs angegebenen Verfahrens zur forensischen Unterscheidung von Menschen- und Tierblut. By various authors. Abdruck aus dem klinischen Jahrbuch, Bd. XIX. Jena: Gustav Fischer, 1908. (Roy. 8vo, pp. 49. M. 150.)

² BRITISH MEDICAL JOURNAL, February 13th, 1903, p. 415.

³ Toxicologie oder die Lehre von den Giften. Von F. A. RossmäSSLER. Wien und Leipzig: A. Hartleben. 1908. (Cr. 8vo, pp. 142. M. 5.)

of unimportant, poisonous substances in a brief but interesting manner, and the book can be recommended to those who only desire to gain a bird's-eye view of the subject. The author states in his preface that, in his opinion, every educated person should know something of poisons and their effects upon the human body, and it has evidently been his object to write a book which would satisfy the requirements of the educated public generally rather than the medical public in particular; he consequently, therefore, avoids technical expressions as far as possible. Perhaps the most complete part of the book is that which treats of poisons derived from plants, and the author has allowed himself more latitude in these chapters than in those devoted to chemical poisons. The chapter dealing with animal alkaloids is very brief and uninteresting. On the whole, however, the book is good as far as it goes, but it does not go very far.

A CONDEMNATION OF ALCOHOL.

We have already noticed several of the contributions to the system of treatment of diseases of digestion and metabolism which is being published in fasciuli by Professor A. Albu, of Berlin, and we have recently received the section on the indications for the administration of alcohol in the treatment of internal diseases, by Professor GEORG ROSENFELD, of Breslau,⁸ which is one of the most uncompromising condemnations of the use of alcohol in disease that has ever appeared in a medical publication not avowedly inspired by temperance principles. According to Professor Rosenfeld the evidence that alcohol is capable of preventing waste is contradictory, and the balance is against it. He believes that to promote the combustion of fat in the body the presence of some other substance is necessary, which he compares to the wood and paper used to start a coal fire, and that carbohydrate is this substance needed for the oxidation of fat. If carbohydrate is absent fat accumulates in the liver. He divides carbohydrates into hepatic and non-hepatic, an example of the latter being seen when sugar is injected into the veins in animals. It is a peculiarity of this non-hepatic sugar that it is oxidizable by animals depancreatized or poisoned by phloridzin. It has a tissue-sparing effect, and in certain people alcohol has the power of converting hepatic into non-hepatic sugar, thus acting as a tissue sparer. This occurs in people who tend to obesity, and the experiments which had positive results were made on Jews who have a well-known predisposition to become fat. Kuelz in one case of diabetes found that alcohol diminished the sugar; according to Hirschfeld it diminishes the nitrogen, but not the sugar; Neubauer, in experiments upon four patients, found that alcohol diminished the acetone and oxybutyric acid, but had no effect on acetone produced in healthy persons by excessive meat diet; Benedict replaced the fat in a carbohydrate-free diet by alcohol, with the result that the acetone was diminished 29 per cent., while in diabetes it reduced the quantity of sugar. Rosenfeld concludes that alcohol acts in the body as a foodstuff, being oxidized completely, and has a tissue-sparing effect which is manifested either after the first doses or in the course of some days. The effect of alcohol upon the circulation is, he says, altogether unfavourable; it in no way deserves its reputation as a stimulant to the heart, it does not raise the blood pressure or change the tone of the small vessels, while its weakening effect on the heart is shown by the quickening of the pulse-rate after exertion and impairment of the power of the heart to regain its normal rate, while the intravascular friction is raised, probably in consequence of increased viscosity of the blood. In collapse and palpitation and the like it may, he thinks, occasionally be helpful by numbing the mind and the vasomotor centre, but its continued use leads to retention of lime in the body, and favours calcification of the arteries. In small doses it increases muscular power, but this rise is followed by a greater fall, while large doses are harmful from the first. Mental processes are slowed by it, and, if in habituated persons it stimulates loquacity, this is probably the result of removing the depression which follows

its use. Small diluted doses increase the secretion of hydrochloric acid, but not of pepsin, while concentrated alcohol checks the flow of gastric juice and excites the secretion of mucus. It diminishes bowel peristalsis, this action being aided by the presence of tannin in wines. Its indications in disease are therefore, according to Professor Rosenfeld, very limited, although it has been used in nearly every malady, either to stimulate the heart or to spare the tissues or to keep up the strength, to promote appetite, or to strengthen the nervous system. He admits that in septic conditions and influenza it lessens the feeling of illness, but he doubts whether it has any other effect; and he states that while no one believes it to influence the local processes in enteric fever and pneumonia, experiments show that it increases the virulence of infective poisons, diminishes the formation of antibodies and of phagocytosis, while clinical experience shows better results where these diseases are treated without alcohol, the results obtained at the Temperance Hospital in London being quoted in support of this last statement. Its only advantage in phthisis is to diminish the patient's consciousness of his illness; in heart disease it only does harm, in stomach diseases its indications are limited, and its effect in relieving the sense of repletion can only be due to its action on the nervous system. Its constipating effect may indicate its use in diarrhoea, but this advantage is only temporary. He believes that it relieves the tenesmus of the bladder in gonorrhoea, but increases the excretion of uric acid. It may be useful in advanced cases of diabetes, where there is great intolerance of carbohydrates. The only benefit that can be derived from it in nervous diseases is as a narcotic, and here, in accordance with the majority of the profession, Professor Rosenfeld prefers other means.

Finally, he concludes that by abstaining from the use of alcohol in the treatment of disease we shall be acting in accordance with the fundamental principle: *Non nocere*.

SNAKE POISONING.

SIR LAUDER BRUNTON has issued, in a volume entitled *On the Poison of Venomous Snakes and the Methods of Preventing Death from their Bite*,⁷ reprints of five papers written conjointly by himself and the late Sir JOSEPH FAYRER, with the co-operation in one case of Major LEONARD ROGERS, I.M.S. The earliest of the papers is dated 1873: the most recent—that on a method of preventing death from snake-bite, capable of common and easy practical application—in 1904. The earlier papers are classical, although we suspect that they are more often quoted at second hand than from the originals. In his preface Sir Lauder Brunton divides the writers of scientific papers into two classes—the “ten-year school,” who systematically neglect all work except that done within the last ten years; and the conscientious workers, who try to find out all that has been done in their own field of investigation, so that their observations may be rightly fitted in and help to build up a solid structure of knowledge. It is in the interests of these conscientious workers that he has published this volume, believing that it may now be difficult to obtain original copies of the papers, and that therefore observations of considerable importance may be overlooked. As an instance he states that Calmette has credited Lacerda with the discovery of the antidotal power of potassium permanganate, and to himself that of chloride of gold, whereas it appears that the first-named salt was used by Fayrer in 1869, the observations being recorded by him in 1872; while the similar action of gold chloride was published by Brunton and Fayrer in 1878. The volume in a way forms a small memorial to the late Sir Joseph Fayrer, and is all the more appropriate because the whole edition of several of his works were destroyed by fire some ten years or more ago.

NOTES ON BOOKS.

THE scope of the *Public Schools and Preparatory Schools Year Book*⁹ is sufficiently indicated by its title. The volume for 1909 is the twentieth. The main part of the book consists of a list of public schools, that term being

⁸ *Sammlung zwanzigloser Abhandlungen aus dem Gebiete der Verdauungs- und Stoffwechsels-Krankheiten.* Herausgegeben von Professor Dr. A. Albu. I. Band. Heft 5. Das Indikationsgebiet des Alkohols bei der Behandlung Innerer Krankheiten. Von Professor Dr. Georg Rosenfeld. Breslau, Halle a. S.: C. Mohrhold. 1908. (Med. 8vo, pp. 18. M. 1.20.)

⁷ London: Macmillan and Co., Limited. 1909. (Demy 8vo, pp. 174. 2s. 6d.)

⁹ *The Public Schools Year Book and Preparatory Schools Year Book, 1909.* London: The Year Book Press (Swan Sonnenschein). (Cr. 8vo pp. 703. 3s. 6d.)

accepted in a liberal sense; particulars as to governing body, list of masters, number of boys, general education, entrance examination, entrance scholarships, and other scholarships, and fees are given. The headmasters' conference last December recommended that this publication should be adopted as its official book of reference, and the next annual issue will appear with this semi-official recognition. There are short articles about Oxford and Cambridge certificate examinations, and on how to enter various professions, including the medical profession, and on Colonial openings; finally, there is a general list of preparatory schools. Altogether the volume will be found useful by any father of sons who has not yet made up his mind what school to select.

The ninth edition of *Saunders's Pocket Medical Formulary*⁹ has been revised by Dr. W. M. POWELL of Philadelphia, who states in the preface that by omitting formulae which had become out of date space has been gained for the introduction of others, illustrating not only the use of approved new remedies, but also the modern application of many old ones. The volume contains a set of prescriptions arranged under an alphabetical list of diseases. It has blank interleaves for additional formulae. A book of this kind will often be found useful by suggesting a new drug or new combination.

*The Year Book of Pharmacy for 1908*¹⁰ presents the usual features of this useful publication, and contains abstracts of the principal papers on pharmaceutical subjects which have appeared in British and foreign journals during the year; these abstracts are arranged under the headings Chemistry, Materia Medica, and Pharmacy. Those grouped as chemistry occupy 220 pages, or over one-third of the entire book; the papers of which a summary is given are of very varied character, dealing with identity and purity tests for a large number of medicinal substances, assay processes for drugs, newly-discovered active principles, etc. The abstracts under the sections Materia Medica and Pharmacy are much fewer in number; the last-named section includes a considerable number of galenic formulae published during the year. The second part of the book is the official account of the proceedings of the British Pharmaceutical Conference held in 1908 at Aberdeen, and includes the full text of the papers presented at that meeting, with the discussions upon them.

In *Analytical Notes, 1908*,¹¹ issued by Messrs. Evans, Sons, Lescher, and Webb, this firm publishes concise accounts of the tests applied in their laboratories to large numbers of commercial specimens of drugs and chemicals. Similar little books of laboratory records are now published by several of the larger firms, and form a very useful indication of the ordinary prevailing standards of purity in drugs. A good deal of importance is evidently attached to maintaining a sufficiently strict limit to the traces of arsenic and lead permissible in chemicals, and far greater purity in this respect prevails now than was the case a few years ago. Of forty-five samples of citric acid only four contained as much as 1 part of arsenic per million, and all but seven contained less than 10 parts of lead per million, the seven containing between 10 and 20 parts. Sodium sulphate contained as much as 4 parts of arsenic per million in four samples out of 100, and sodium bicarbonate conformed to a very similar standard. Figures are given for about 150 different drugs and chemicals.

THE Belgian Government is making arrangements for the establishment of an Institute of Tropical Medicine at Antwerp.

THE annual report of the Trained Nurses' Annuity Fund for 1908 states that in view of the Old Age Pension Act the regulations have been revised, and it is hoped that in future the society will be more free to help younger nurses who become incapacitated. A candidate for an annuity must have had at least three years' training and seven years' subsequent nursing, have attained the age of 40, and be more or less incapacitated for work. There is, however, at present no vacant annuity. Further particulars can be obtained on application to Dr. A. Ogier Ward, 73, Cheapside, E.C.

MEDICINAL AND DIETETIC PREPARATIONS.

Tablets for the Production of Lotions.

UNDER the name "Soltabs," Messrs. Hewlett and Son, Ltd. (Charlotte Street, London, E.C.), are supplying a series of soluble tablets for the production of lotions. These are distinguished by their shape from tablets for internal administration. We have examined samples of nasal eucalyptol comp. which have been submitted, consisting of borax and sodium bicarbonate with several antiseptics, and find that they can be readily crushed or broken, and dissolve without difficulty to form a clear solution.

New Theobromine Compounds.

We have received from Messrs. Widenmann, Broicher, and Co. (33, Lime Street, London, E.C.), samples of two new derivatives of theobromine introduced by Messrs. Zimmer and Co., Frankfurt. The first of these is called Eustenine, and is theobromine sodium iodide $C_7H_7N_3O_5NaI$; the formula shows that it contains 36 per cent. of iodine, or 43 per cent. of sodium iodide. Eustenine is recommended for use in arterio-sclerosis and allied conditions. We found it to be a white powder of strongly alkaline reaction, soluble in water, the solution being stable with alkalis, but decomposed after a short time by acids, theobromine being deposited in crystals. The other new theobromine derivative, Theolactin, is also alkaline in reaction, but its solution is less stable: it must be dissolved in warm water, and on cooling the solution theobromine gradually separates unless additional alkali is added. This compound is theobromine sodium lactate, and therefore very similar in constitution to diuretin. It is a granular white powder, very hygroscopic in nature, and is recommended as a diuretic free from injurious action on the heart, which may be employed alternatively with other compounds when it is desired to change the diuretic administered in any given case.

Evaporating Skin Lotions.

We have received samples of a number of lotions prepared by Messrs. C. J. Hewlett and Son, Ltd. (Charlotte Street, London, E.C.), intended for use in cases of eczema in which fatty bases are undesirable. Various formulae are employed, including sulphur, zinc oxide, resorcin, solution of coal tar, and ichthyol. The lotions are of a slightly gelatinous consistency, and when applied to the skin, the vehicle, which is partly alcoholic, evaporates fairly rapidly, leaving the medicaments in a dry film, which is not readily rubbed off.

Tablets of Glycerophosphates with Haemoglobin.

In spite of the doubts that have been cast on the superiority of glycerophosphates to inorganic phosphates, these compounds continue to find much favour, and the number of ready-made combinations in which they are supplied is continually increasing. A useful form for their exhibition is provided by the tablets of compound glycerophosphates with haemoglobin, prepared by Messrs. C. J. Hewlett and Son, Ltd. (Charlotte Street, London, E.C.), a sample of which we have examined. These are sugar-coated tablets containing glycerophosphates of calcium, potassium, sodium, iron, and magnesium, with caffeine, strychnine, and haemoglobin. There are obvious conveniences in the tablet form for such a medicine, which is likely to be ordered for patients who are following their ordinary occupations.

MEDICAL AND SURGICAL APPLIANCES.

Tablets for Testing Urine.

VARIOUS devices have been introduced from time to time for the purpose of simplifying the clinical testing of urine, especially for sugar and albumen, and perhaps the most successful of these is the employment of tablets of known strength for preparing the respective agents at the moment when they are required. Mr. E. Merck (16, Jewry Street, London, E.C.) has submitted samples of a number of such tablets which he has recently placed on the market, and our examination of these has shown them to be very satisfactory for the purpose. They include tablets for the preparation of Fehling's solution for the detection of quantitative determination of glucose, and tablets for the production of Esbach's Reagent, Riegler's Reagent, and acid-ferricyanide solution, for the detection of albumen; the first named of these three can also be used for its approximate determination by means of an albumino-meter.

Nova et Vetera.

CALENTURE.

EVERY student of English literature must have come across in it many allusions to a strange malady called "Calenture," a term which appears to have been introduced into our language at the end of Elizabeth's reign, when our seamen came into communication with the Spaniards. The word is derived from the Spanish *calentura*, fever, and this from the Latin *calere*, to be hot.

One of the earliest reference to this malady is to be found in Nashe's *Christ's Tears over Jerusalem*, 1593: "Then (as the possessed with the Calenture) thou shalt offer to leave." Another occurs in the *London Prodigal*, 1605: "Such men die mad as of a calenture." In Hawkins's *Voyages in the South Seas*, 1622, we have evidence that calms at sea were thought to be favourable to the production of the disease: "To avoid the calmes, which . . . breed calentures, which we call burning fevers." Apparently the fever was supposed to have some effect on the liver, for in Massinger's play, *The Fatal Dowry* (Act. III, sc. 1), 1632, Charalois is made to say:

Thou dost strike
A doubtful coldness to my heart's high heat,
And shrink'st my liver like the calenture.

Defoe has made us familiar with the word "calenture" from our boyhood. In *Robinson Crusoe* we read, "Yet even in this voyage I had my misfortunes too; particularly that I was continually sick, being thrown into a violent calenture by the excessive heat of the climate." The disease was believed especially to attack sailors in the tropics and and to cause a delirium in which the sufferers fancy the sea to be green fields, and desire to leap into it.

So by a calenture misled,
The mariner with rapture sees
On the smooth ocean's azure bed,
Enamelled fields and verdant trees.

Soon after Swift wrote these lines, Pope and Theobald were in hot dispute over the meaning of a sentence in *Henry V* (ii, 3) describing the death of Falstaff. In the folios we read, "and a Table of green fields," but Theobald in his edition of the play altered the words to "and a' babbled of green fields." This interpretation was rejected by Pope, who maintained that the words were part of a stage direction, which had crept into the text from the margin, Greenfield being the name of a property man. Theobald, in defence of his correction, remarked: "It is certainly observable of People near Death, when they are delirious by a Fever that they talk of moving; as it is of Those in a Calenture, that they have their Heads run on green Fields." Wordsworth in his poem, *The Brothers*, gives an imaginary description of a sailor who on a voyage looks over the side of the vessel and sees in the deep the verdant hills of his native country and sheep grazing on them. In a footnote, it is stated, "This description of the Calenture is sketched from an imperfect recollection of an admirable one in prose by Mr. Gilbert, author of *The Hurricane*." Somewhat recently, in a magazine now defunct, the following curious story was told as a fact. During a dead calm at sea a boy on a ship who had been remarkable on the voyage for his high spirits and love for practical joking was observed one day to be despondent, listless, and apparently in a state of ill-health. He would not own, though, that he was unwell, and when spoken to appeared to be inattentive to what was said and preoccupied in mind. On one occasion, when asked how he was, he burst into tears, moved away from his interrogator, and gazed intently into the sea. An old sailor advised that he should be taken below, saying, "The calenture has come upon him." Almost at that instant, the boy flung himself into the sea. He was rescued, however, and the contact with the cold water seemed to have a beneficial effect, for he shortly afterwards regained his cheerfulness. "He told us," says the narrator, "that he had all that day been

thinking of home, until he had persuaded himself that he saw his mother's cottage in the waves, and the trees and green fields glittering in the sunshine around it, and that he could not resist the desire to leap to them again!"

According to old medical writers, calenture is a species of phrenitis—a term which has been used in the past to signify phrensy, delirium, brain fever, and encephalitis. An account of the complaint is given by Bonetus, and also by Oliver and Stubbs. Oliver says: "In the month of Aug., 1693, I was called upon about four a Clock in the morning to see a Sailor on board the *Albemarle*, Man of War, in a violent Calenture. . . . When I saw him first I found him in the hands of 3 or 4 of his Comrades, who were hardly able to manage him, because of his strugglings and constant endeavours to get from them. I observed he very often cried out he would go into the green fields, his looks were as furious and wild as those of a Lyon, and every now and then he would heartily curse those that held him." It is then related how the man was bled, and recovered with some weakness from loss of blood. "This was the only Calenture," the writer adds, "I saw all the while I was in the Fleet for near three years, two summers of which I served in the Mediterranean, and this happened in the Bay of Biscay, in the Latitude of 47, in the month of August. They are, I hear, more frequent in warmer climates, tho. very often undiscovered."

"The reason I imagine to be this. When they are seized with the violent Heat and Disorder which for the most happens in the night, they steal privately overboard into the Sea, imagining they're going into green Fields. . . .

"This Distemper I am of opinion is what we call a Phrenitis, occasioned by a more than ordinary Effervescence and Heat of the Blood, which distracting and confounding, if not inflaming the Animal Spirits, the proper and immediate ministers of the mind, is the cause of all those irregular motions, violent explosions, and convulsions." (*Philosoph. Trans.*, vol. xxiv.)

Calenture, when the term was not employed in the general sense of fever or ardour or zeal, seems to have been what is now called thermic fever or sunstroke occurring in sailors at sea. In bygone times, when there were no steamboats sailors were much more exposed to the burning heat of the sun than they are now, especially during calms at sea. Their sufferings must have been terrible, and it can easily be conceived that they frequently became delirious and were subject to sensory illusions. Indeed, it has been said that sailors becalmed under a vertical sun in the midst of the wide ocean have listened in trembling wonder to what they imagined to be the chimes of their own village bells. In such solitude and distress it would be likely for home-loving English sailors to crave for a sight of their native country, and if delirious their "heads" to "run on green Fields."

There may be some truth in what Keats has observed that when we are ailing we are more sensible of the beauties of Nature. While suffering from consumption, he remarked to a friend, "Like poor Falstaff, though I do not 'babble' I think of green fields."

Again, it must be remembered that ships in former days were often ill-provisioned, so that sailors suffered much from hunger and thirst. Shipwrecked mariners, it is well known, either from the effects of want of food or water, or both, get delirious, have illusions, and sometimes throw themselves overboard. The captain of a wrecked vessel, who suffered from starvation but not from thirst, told Goldsmith that "when his health was almost destroyed, a thousand strange images rose upon his mind, and every one of his senses began to bring him wrong information." Intense thirst also induces great nervous excitability and delirium. Experiments made by Harless in Munich showed that the nerves gain an extraordinary increase in their excitability as their proportion of water decreases.

It would be interesting to know if sailors ever now, as the result of heat upon the body, or hunger, or thirst, manifest a desire to cast themselves into the sea, believing it to be green fields. The present writer has been unable to find out from seafarers that they have any knowledge of a fever at sea producing such a peculiar form of delirium as is ascribed by old authors to calenture.

EDWARD KNIGHT, L.R.C.P. and S.Edin.

THE TWENTIETH CENTURY DISEASE.

ANTINEURASTHIN, A BRAIN AND NERVE FOOD.

READERS of daily or weekly papers or magazines who allow their eyes occasionally to travel over the advertisement pages of these journals can hardly fail to have seen somewhat frequently a lengthy advertisement of a preparation called Dr. Hartmann's Antineurasthin. The advertisement is usually headed "The Twentieth Century Disease." This, it appears, is neurasthenia, and the various stages of its manifestations are set out in a sort of table, beginning with "Sensitiveness" and ending with "Suicidal Tendency." Antineurasthin, referred to as "this marvellous twentieth century brain and nerve food discovery," is put forward as a specific for the cure of neurasthenia.

Dr. Hartmann's discovery is one that should personally and very deeply interest brain-workers in all walks of life. Every day are heard and seen all too serious evidences of the undue strain of their intense work on the vital power of the body. And now, on the highest possible authority, it is heralded that science has proved equal to the stern necessity which demanded the discovery of "Antineurasthin," the brain and nerve food.

For greater convenience "Antineurasthin" is compressed into small tablets, and although its beneficial effect on the brain and senses is so immediate, yet there is none of the depressing reaction that follows the administration of artificial drug stimulants, "Antineurasthin" being a special brain and nerve nutrient, and not a brain and nerve drug-irritant. No longer need the brain-worker struggle on under the cloud of fear of failing powers of brain and body. He or she may, by including "Antineurasthin" as an article vitally necessary in the daily diet, build up and maintain that perfect balance of mental and physical power which alone can uphold health and happiness.

It appears that this article was sold in Germany before being introduced here, and it was included in the series of proprietary preparations analysed by Dr. Zernik, whose results have been quoted from in our columns from time to time. According to Zernik's analysis¹ it consists of dry yolk of egg, milk sugar, a small quantity of starch, dextrin, and an aromatic substance.

A detailed quantitative analysis of "Antineurasthin" as sold in this country gave the results described below. A 4s. 6d. box contained twenty-four tablets, having an average weight of 30½ grains each. The directions are:

"To be taken when and as required, particularly before or after great exertions (bodily and mental); in all cases of nervous disorders and mental affections, general debility, etc."

Usual dose 3-4 tablets a day between meals. Antineurasthin contains no injurious ingredients, and is therefore absolutely harmless to the most delicate, even if taken in large quantities.

Analysis showed the presence of:

Proteid...	26.4 per cent.
Fat	2.5 "
Sugar of milk	32.8 "
Ash	5.7 "
Water	8.3 "
Gum	...	about	2.0 "
Aromatic substances	traces "
Potato starch (by difference)	about	22.0	"

The material of the tablets is nearly white, with yellow particles like dried egg-yolk distributed through it; extraction with appropriate solvents proved a fair trace of lecithin to be present; if the whole of the fat present were derived from egg-yolk it would represent 3.8 per cent. of dried yolk, equivalent to 7.7 per cent. of fresh liquid yolk in the tablets; this accounts for 1.3 out of the 26.4 per cent. of proteid. Sulphur in organic combination was found to be present to the extent of 0.09 per cent.; sulphur is practically absent from the yolk, but occurs in the white of eggs, and the amount found corresponds to 5.4 per cent. of dried, or about 38.6 per cent. of liquid, egg-albumin in the tablet; a further 5.1 out of the 26.4 per cent. of proteid is thus accounted for. This leaves 20 per cent. of proteid, and this stands in about the same ratio to 32.8 per cent. of milk sugar, and about 5 per cent. of ash (deducting the ash of the egg and gum), as corresponds to the composition of a dried separated milk. The ash consisted principally of calcium phosphate, like the ash of milk. The aromatic substances appeared to include a trace of vanilla and of some other substance that could not be identified; these are probably added to serve at the same time as flavouring agents and preservatives.

The starch was seen by the microscope to be very abundant, corresponding in appearance to the amount required by difference. On the above assumptions the composition of the tablets would be approximately:

Dry yolk of egg...	3.8 per cent.
Dry white of egg	5.4 "
Dry separated milk	57.8 "
Gum	2.0 "
Potato starch	22.7 "
Moisture	8.3 "
Aromatic substances	traces.

The daily dose of four tablets, or 122 grains, would, according to this formula, contain the equivalent of 10 grains of yolk and 43 grains of white of egg (not dried); the ratio between these is about the same as exists in an average egg, and the two may be put together and regarded as about a teaspoonful of fresh egg; in addition, the daily dose would represent about 2 oz., or a quarter of a tumblerful, of separated milk and a little starch.

THE BRITISH MEDICAL BENEVOLENT FUND.

At the February meeting of the Committee twenty cases were considered and grants amounting to £190 made to sixteen of the applicants. Appended is an abstract of the cases relieved:

1. Widow, aged 57, of L.R.C.P. Edin. No income; endeavours to support herself by letting lodgings, but has great difficulty in making ends meet. Only child unable to help. Relieved six times, £70. Voted, £12.

2. Widow, aged 84, of M.D. Aberd. Quite unprovided for at husband's death sixteen years ago and dependent on two daughters who are governesses. Voted £18.

3. Widow, aged 50, of L.R.C.P. Irel., L.R.C.S. Edin. Ought to receive £40 a year from property in Ireland, but tenants refuse to pay the rent. Three children unable to help. Voted £12.

4. Daughter, aged 48, of L.R.C.P., L.R.C.S. Edin. Has maintained herself for several years by teaching, but has recently been operated upon for malignant disease, and is now practically destitute. Voted £18.

5. Daughter, aged 47, of M.R.C.S. Eng. Used to be fairly provided for, but, owing to great depreciation of her investments and unavoidable expenses due to ill-health and two surgical operations, is now obliged to seek a home with a relation who can ill afford to help. Voted £10.

6. M.D. Glas., aged 70. Has been incapacitated for the last nine months, and is now at an end of his resources. No children. Voted £12.

7. Daughter, aged 41, of late M.R.C.S. After father's death took to nursing, but contracted blood poisoning and has never recovered; is now permanently incapacitated and quite deaf. Voted £12.

8. Daughter, aged 57, of M.D. Edin. Since father's death 40 years ago has supported herself by teaching, but finds it increasingly difficult to do so, and is now broken down in health and ordered to take a rest. Voted £12.

9. M.R.C.S. Eng., aged 66. Quite incapacitated for the last year; income less than £1 a week, derived from sickness allowance and a small Poor Law pension. Three daughters, but only one self-supporting, the other two being chronic invalids. Voted £18.

10. Widow, aged 67, of F.R.C.S. Eng. Only income, £20 a year; no children, health failing. Relieved five times, £40. Voted £5.

11. Daughter, aged 61, of late M.R.C.S., L.R.C.P. Income £30 a year, derived from two charitable institutions. Is quite blind and in bad health. Relieved four times, £32. Voted £10.

12. Widow, aged 69, of M.R.C.S., L.S.A. Since husband's death several years ago supported herself by acting as nurse-companion, but now finds increasing difficulty in obtaining cases, and has exhausted her small savings. No children. Relieved four times, £33. Voted £10.

13. Widow, aged 40, of M.D.R.U.I. Quite unprovided for at husband's death ten years ago. Now acts as a housekeeper, receiving a home for herself and boy (a candidate for Epsom College) in lieu of salary. Relieved ten times, £119. Voted £12.

14. Daughter, aged 52, of late M.R.C.S. Was left an orphan, quite unprovided for, when 5 years old, and now acts as a companion but receives no salary and requires a little help for unavoidable expenses. Relieved once, £5. Voted £5.

15. Widow, aged 47, of M.B. Durh., M.R.C.S. No income; lets lodgings. Two children, one a boy at Epsom College. Relieved once, £12. Voted £12.

16. Daughter, aged 57, of late L.S.A. Endeavours to support herself by letting lodgings; no other source of income. Relieved once, £10. Voted £12.

¹ BRITISH MEDICAL JOURNAL, November 3rd, 1903, p. 1223.

REPORT

OF THE

Royal Commission on the Poor Laws and Relief of Distress.

[SECOND NOTICE.]

We gave last week (pages 479-484) an account of the general scope of the Majority and Minority Reports of the Royal Commission on the Poor Laws and Relief of Distress.* In particular full details were quoted with regard to the suggestions of both reports as to medical relief; there remain, however, many other matters in these very voluminous reports to which we propose to refer as occasion serves. Many evils in the present system are disclosed, and far-reaching changes are suggested in both reports. Indeed, as we have already pointed out, the majority and minority agree to a very large extent as to the evils existing, the chief differences being as to the remedies which should be suggested. The task of stating the points of agreement is considerably simplified if we accept the statement put forward by Mr. and Mrs. Sidney Webb in the volume entitled, *The Break-up of the Poor Law*: it is the first of two volumes "edited with introduction by Sidney and Beatrice Webb,"† and consists of the first twelve chapters of the Minority Report, without the notes and references, but containing an introduction nine pages long, which is an expression of the views held by Mr. and Mrs. Sidney Webb. In this introduction we find the following observations upon the points of agreement:

Although the Majority Report is flanked by half a dozen dissenters—of which the longest is here republished—the members of the Commission are remarkable in the extent of their revolutionary unanimity. All the Commissioners, without exception, agree that drastic changes in the Poor Law and its administration are urgently required: all agree that the "principles of 1834," whatever they once were, are now hopelessly antiquated and inapplicable to the present state of things; all agree even in discarding the very terminology of the Poor Law, to which administrators and paupers alike have grown accustomed, in order to mark the completeness of the break from the past; all agree that the boards of guardians in town and country alike must imperatively and immediately be replaced by some other authority; all agree in condemning, and in recommending for abolition, the general mixed workhouse, which has been for seventy-five years the characteristic feature of the English Poor Law administration; all agree that the treatment of the children, the sick, and the aged needs to be greatly improved. Similarly, all but two out of the eighteen agree that the union area, which has dominated English administrative geography for more than half a century, must disappear from the map; that the future unit of local administration must be the county borough and the county; and that the county borough councils and county councils must add to their other functions those hitherto discharged by the boards of guardians. There has, we think, never been a representative Royal Commission, constituted of members of such diverse opinions, dealing with a subject of so great an extent, and of far-reaching importance, which has, after three years' investigation, found itself agreeing with so much unanimity to conclusions of such sweeping character.

Authors' Footnote.—"The administrators of the Poor Law," we are told in the Majority Report, "are, in fact, endeavouring to apply the rigid system of 1834 to a condition of affairs which it was never intended to meet. What is wanted is not to abolish the Poor Law, but to modify, strengthen, and humanize the Poor Law" (par. 537 of Chapter I of Part VI of Majority Report).

The rest of the introduction is devoted to a critical review of the recommendations of the Majority Report. The minority resent the reflections made upon the personal shortcomings of the Poor Law guardians, and appear disposed to defend them on the ground mainly that some of them are actuated by the best motives, and have given much time and energy to the work, and that all have been hampered and interfered with by the creation of other authorities whose duties overlap those of the guardians.

The minority declare that the recommendations of the majority propose the setting-up again of what is practically the same sort of Poor Law relief with new members under another name.

The majority, as was stated last week, propose to place the county council in supreme control in each county, and to require it to appoint special committees for dealing with Public Assistance. The minority propose very much the same thing, that is to say:

"That the boards of guardians in England, Wales, and Ireland, and (at any rate as far as Poor Law functions are concerned) the parish councils in Scotland, together with all combinations of these bodies, should be abolished.

"That the property and liabilities, powers and duties of these Destitution Authorities should be transferred (subject to the necessary adjustments) to the county and county borough councils, strengthened in numbers as may be deemed necessary for their enlarged duties; with suitable modifications to provide for the special circumstances of Scotland and Ireland, and for the cases of the metropolitan boroughs, the non-county boroughs over 10,000 in population, and the urban districts over 20,000 in population."

OVERLAPPING OF AGENCIES PROVIDING MEDICAL ASSISTANCE.

The Majority Report refers to the want of co-operation and consequent overlapping of effort of the various agencies supplying non-institutional medical treatment to the poorer classes; such treatment is supplied by the guardians, sanitary authorities, education authorities, out-patient departments of voluntary hospitals, free dispensaries, provident dispensaries, medical clubs, and friendly societies. It is stated that, except to a very limited extent, there is no real or effective co-operation between the Poor Law and other agencies providing medical assistance, and the Commissioners recommend that there should be co-operation.

Out-patients.

With regard to out-patients the report has the following observations on the right sphere of the voluntary hospital in regard to out-patients:

This problem, in our opinion, lies at the very entrance to any radical reform of the system of medical assistance. In the metropolis, as we have shown, the out-patient departments of the hospitals steadily and enormously enlarge their sphere. Much of this increase is due, rightly and properly, on the one hand to increase in population, and the increasing facility with which the poor in country districts can travel to London, but chiefly to the expensive equipment for dealing with special diseases which science has now placed in the doctor's hands. But these valid grounds for an increase in the work of the out-patient department render it all the more necessary to save them from certain abuses of which we have had ample evidence.

In the first place, the out-patient departments are dealing with a large number of cases for whose treatment the Poor Law authorities are, or should be, responsible. Thus, our special investigator, Miss Roberts, concludes that, if the three hospitals selected for her inquiry be fair samples, "at least 11 per cent. of out-patients at the voluntary (general) hospitals in London are actually Poor Law cases, being in receipt of some form of Poor Law assistance either at the very time they are treated, or within a half year of treatment." Under a co-ordinated system, it might be expedient to refer certain pauper cases to the out-patient department for a second opinion, or for special treatment, but this does not appear to be done to any great extent at present. Accordingly, it may be said that the out-patient departments are performing a great deal of work which should properly be done by the Public Assistance Authorities.

In the second place, it is for consideration whether the Public Assistance Authorities should not also deal with the two following classes of cases, which at present receive treatment from the out-patient departments:

- (a) Persons who are suffering from chronic ailments.
- (b) Persons whose home conditions will not allow them to reap any commensurate benefit from such treatment.

In the third place, the benefits of the out-patient departments are being extended to:

- (a) The well-to-do who can afford to pay private practitioners.
- (b) Persons sufficiently able to join a provident institution.

189. Until, therefore, the work of the out-patient department is delimited in such a way as to prevent overlapping between its sphere and that of the Public Assistance Authority, and to leave full scope for private practice and provident effort, any endeavour to reform the system of public medical assistance will be locally thwarted. Indeed, all attempts to create order out of the present chaos will be disappointing. Even in the interests of the out-patient departments themselves a reform

* To be purchased, either directly or through any bookseller, from Wymann and Sons (London), Oliver and Boyd (Edinburgh), and E. Poysonby (Dublin). Gd. 4s. 6d., Fwd. 5s. 6d.

† Vol. I, *The Break-up of the Poor Law*, Vol. II, *The Public Organization of the Labour Market*. Containing the remainder of the Minority Report. London: Longmans, Green and Co. 1908. Demy 8vo, pp. 613 and 359. 7s. 6d. and 5s. respectively.

appears to be expedient in order to secure the greatest benefits from the treatment which they so lavishly bestow, and to prevent those benefits from being abused by the well-to-do. Suggestions for remedying the abuses of the out-patient department have been laid before us by many witnesses, but by none more fully than the representatives of the British Medical Association. We are convinced with them that a strenuous effort should be made to circumscribe the work of the out-patient departments. They should be used almost exclusively for:

- (1) Casualties.
- (2) Consultations.
- (3) Cases requiring expensive equipment for the treatment of special diseases and defects.

To this end the "letter" system should be thoroughly reformed or abolished, and, except for casualties, the recommendation of a medical officer or private practitioner substituted.

190. We recommend, therefore, that the work of the out-patient departments of the voluntary hospitals should be re-organized on these lines; that they should be protected from abuse by the well-to-do; and that a strong endeavour should be made to bring their work into co-operation with that of the new organization of medical assistance which we propose to set up.

Education Authorities.

The Majority Report calls attention to the fact that under the Education (Administrative Provisions) Act, 1907, the education authorities have far-reaching powers for providing medical assistance to children out of the rates. On this subject the report contains the following observations:

We desire also to draw special attention to the position created by the Education (Administrative Provisions) Act, 1907, to which we have already referred. Under that Act the Education Authorities have far-reaching powers of providing medical assistance to school children out of the rates. Unless their work in this respect is co-ordinated with that of the Public Assistance Authorities, the evils of overlapping and consequent waste of effort and money will be accentuated. For example, we have recommended that there should be more medical inspection of all children under the Public Assistance Authorities. Of the 38,000 children of school age who were, on January 1st, 1907, being maintained in Poor Law establishments, about 18,000 were attending public elementary schools. In addition, out of the 171,000 children in receipt of out relief on that date,¹ it may be said that practically all who were of school age were attending such schools. In the absence of co-operation, therefore, it is conceivable that all these children might, simultaneously, be the subject of medical inspection on the part of both the Public Assistance and the Education Authorities, and a large proportion of the children might, likewise, be receiving simultaneously two kinds of medical treatment.

Such a contingency would be regrettable, even if it were to obtain in only a modified degree. We are, however, hopeful that it may be possible to avoid it altogether. We are pleased to observe from the Board of Education Memorandum, dated November 22nd, 1907, explaining to the Education Authorities their duties as to medical inspection and treatment of school children, that the principle of co-operation with other local authorities is not lost sight of. For example, it is recommended that "the work of medical inspection should be carried out in intimate conjunction with the public health authorities, and under the direct supervision of the medical officer of health." Again, as regards the treatment of children by the Education Authorities, it is recommended that it be done, meantime, "through such agencies as are conveniently available."

192. We have here an opportunity of establishing at the outset, an effective method of co-operation, or division of labour, in the performance of a public duty. The medical inspection of pauper children attending public elementary schools may, no doubt, be effectively carried out as recommended in the Board of Education Memorandum, but any treatment for diseases required by such children would, we think, be provided through the agency of the Public Assistance Authorities.

Further, we think that this principle should be applied to all children attending public elementary schools. Thus, the Sanitary Authorities, whose functions are mainly concerned with the prevention of infectious disease, would be responsible for the medical inspection of all the children. On the other hand, the Public Assistance Authority, whose functions would be to provide medical treatment, would provide such treatment for all school children, so far as they require to be treated at the expense of the rates.

VACCINATION AND REGISTRATION OF BIRTHS, DEATHS, AND MARRIAGES.

The Commissioners recommend that the duties of boards of guardians in relation to vaccination and registration should be handed over to committees of county and borough councils dealing with kindred matters. They point out that these duties are altogether extraneous to the work of public assistance. These suggestions will meet

with less opposition and adverse criticism than many others. It has long been contended that the administration of the Vaccination Acts by Poor Law guardians is an anomaly. Whatever becomes of boards of guardians in the legislative measures which it is to be supposed will follow the issue of this report, the administration of these important matters will now almost certainly be undertaken by the authorities more intimately concerned. In the case of vaccination it cannot be doubted that the public health department is that upon which the duties of administration naturally devolve. It is certain also that benefit would follow the change, inasmuch as the public would be more favourably impressed by measures of preventive medicine controlled and regulated by the properly constituted health authority.

The Commissioners have drawn up a list of complaints against the Poor Law system, which they describe as the leading defects of the system. Clause IV of the summary of these defects refers to "The lack of intelligent uniformity in the application of principles and in general administration." The manner in which guardians have carried out their duties in relation to vaccination gives strong support to this view of the Commissioners. Absence of intelligent uniformity was a marked feature quite recently when the question of the remuneration of public vaccinators was considered by guardians throughout the country. The result is variation amounting in many instances from 50 to 100 per cent. in the fees paid for precisely the same work under similar conditions. The removal of the administration of vaccination to a committee not concerned with Poor Law relief or "public assistance" will prevent the future use of vaccination fees as an excuse for and set-off against absurdly inadequate payment for medical services to the necessitous poor.

Regarding the registration of births, deaths, and marriages, the Commissioners state that the Registrar-General considers that a closer relation between the sanitary and registration districts is highly desirable. Every one with any knowledge of the subject will agree with this. Registration districts should be coterminous with sanitary areas. The duties of guardians in connexion with registration are very limited. They simply appoint and pay the officers. Thus the duty is largely one of patronage. The suggested change will make the returns more useful for comparative statistics. The better selection of suitable officers for the work is another advantage which the change is calculated to effect, for mere personal and local influences would be less in evidence. In both these instances the desirability of the suggested change does not depend merely on the manner in which the duties have hitherto been performed by the guardians. Time was when the Poor Law guardians had among their duties the suppression of nuisances, the administration of sanitary measures, and the treatment of infectious diseases. The changes contemplated in regard to vaccination and registration are in natural sequence and are demanded by the same considerations which brought about the previous alterations. A public assistance authority for each county or county borough taking over the present duties of boards of guardians will not be weakened in any way by the transference of vaccination and registration to their proper spheres.

INFANT MORTALITY IN POOR LAW INSTITUTIONS.

It will come as a surprise to most persons to learn that more than 8,000 children are born every year in Poor Law institutions and remain for a shorter or longer time as inmates. Up to the year 1907 no accurate information on the death-rate of these infants was forthcoming. It was perhaps assumed that if the maternal mortality were not excessive that of the infants would follow the same law. This hypothesis has been tested by a private inquiry instituted by a member of the Commission. Forms were sent out to all the unions in England and Wales, and 450 of these gave a voluntary response. They did so in perfect good faith, and it would be manifestly unfair to single out from these returns any particular institution for either praise or blame, but the total figures which are given in the Minority Report, when classified after the manner of the Registrar-General for the population at large, throw a light on the condition of the children in these places that is both unexpected and unwelcome. We have not discovered any mention of these returns in the Majority Report, but until an index has been published it is a little

¹ Thirty-sixth Annual Report of Local Government Board, 1906-7, pp. cxxiii-v.

difficult to prove the negative; independent investigations have, however, led us to a reluctant acquiescence in the truth of at least the general statements made, which are of a nature to call for immediate action on the part of every right-minded person, no matter what political or other views he may hold as to the general question of Poor Law reform.

The scope of the inquiry is indicated by the remarks in the Minority Report (p. 781):

We were, therefore, interested in the mortality statistics of the 8,483 infants who were born during 1907 in the workhouses of the 450 unions responding to the inquiry made by one of our members. Out of these 8,483 infants no fewer than 1,050 actually died on the premises before attaining 1 year. The Registrar-General, as is well known, gives, for the whole population, the number of babies, out of every 1,000 born, who die before the expiration of certain days, weeks, and months of the first year of life. Similarly, there has been worked out for these 8,483 babies born in 450 of the Poor Law institutions in England and Wales during 1907, taking only the deaths actually occurring in the institutions, the proportion dying within corresponding periods of their first year—making the assumption, for the purpose of comparison of death-rates, that those who left the workhouse within the year had a death-rate equal to those remaining in the institution.

The shorter table gives the result at a glance.

TABLE II.—Infantile Deaths out of every 1,000 born.

Ages at Death.	Workhouses outside London.		London Workhouses.		England and Wales, 1906.	
	Legitimate.	Illegitimate.	Legitimate.	Illegitimate.	Legitimate.	Illegitimate.
Under 1 month	72.6	78.2	85.5	66.7	41.9	37.0
1 to 3 months	72.8	85.9	57.1	116.2	25.7	24.6
3 to 6 "	76.8	56.4	70.9	107.6	27.0	27.3
6 to 9 "	30.8	28.7	48.9	72.2	20.8	21.7
9 to 12 "	58.7	19.4	57.2	29.3	17.1	19.3
	311.7	268.6	319.6	392.0	132.5	129.9
Number of infants on whose experience from birth the above rates are based.	1,479	4,421	1,002	1,581		

This result appears to us somewhat startling. The infantile mortality in the population as a whole, exposed to all dangers of inadequate medical attendance and nursing, lack of sufficient food, warmth, and care, and parental ignorance and neglect, is admittedly excessive. The corresponding mortality among the infants in the Poor Law institutions, where all these dangers may be supposed to be absent, is between two and three times as great. Out of every 1,000 babies born in the population at large, 25 die within a week and 132 are dead by the end of the first year. For every 1,000 children born in the Poor Law institutions, 40 or 45 die within a week, and, assuming the mortality among those who are discharged to be the same as those remaining, no fewer than 268 or 392 will be found to have died by the end of the year, the number varying according to whether we take the experience of the Poor Law institutions for legitimates or for illegitimates, in the metropolis or elsewhere.

In the very few Scottish and Irish workhouses that gave returns, the mortality was, on the whole, greater than in England and Wales. It is interesting to compare these figures with those of other institutions in which women are delivered. On this subject the report states:

We have not been able to obtain exactly corresponding statistics for the infants born in voluntary maternity hospitals. But their annual reports give the total number of births and infantile deaths within the institution, and the stay in those of the metropolis is so very generally a fortnight, that these statistics may be compared roughly with the deaths in the Poor Law institutions during that period after birth. The proportion of infantile deaths to the births during 1907 was, in the City of London Lying-in Hospital, 20.49 per 1,000; in the East End Mothers' Home, 21.07 per 1,000; in the Queen Charlotte's Lying-in Hospital, 26.1 per 1,000; and in the General Lying-in Hospital, 59.3 per 1,000; or, taken together, out of 3,414 births, 30 per 1,000—to be compared with the 46 to 53 per 1,000 recorded of the Poor Law institutions as a whole. In the well-known Rotunda Hospital at Dublin, out of 2,262 births in 1906, there died in hospital only 30 infants; in 1907, out of 2,318, only 21 infants. The usual stay in hospital is, however, apparently only seven

days, so that the extraordinarily small proportion of infantile deaths—13, or 9 per 1,000—must be compared with the 25 per 1,000 for England and Wales, and the 40.1 to 44.9 per 1,000 of the workhouses for the first week.

A still more interesting comparison is to be found in the death-rate of infants born in their own homes, even in a very poor district. No one can claim that West Ham is an ideal residence. Yet the report says:

One of our members obtained, for the purposes of comparison, exact statistics of all the babies born during the same year (1907) under the care of the Plaistow Maternity Charity, an organization for providing gratuitous midwifery attendance at birth, and for the first fortnight afterwards, in the mother's own home, in one of the most poverty-stricken districts of West Ham.

Statistics were thus obtained for no fewer than 3,005 infants, all of them born in households having incomes of no more than 21s. a week. Of these, there died within the first fortnight only 47, or 15.33 per 1,000 births. In the four large voluntary maternity hospitals in the metropolis of which we had statistics the infantile mortality taken together was, for the first fortnight, 30 per 1,000 births. This, too, was nearly the infantile death-rate for the first fortnight among the whole population (namely, 31.1). In the Poor Law institutions of the metropolis the corresponding death-rate was, among legitimate children, 47.2, and among illegitimate children 46.1 per 1,000 births. In the Poor Law institutions of the metropolis the corresponding death-rate was, among legitimate children, 47.2, and among illegitimate children 53.6 per 1,000 births. The 3,005 infants attended to in their homes, poor and wretched as were these homes, by the competent nurses of the Plaistow Maternity Charity had therefore a death-rate, during the first fortnight after birth, considerably less than that in the most successful of the voluntary hospitals, and less than a third of that in the Poor Law institutions.

To return to the table we note in the first instance:

It is interesting to observe that these heavy infantile death-rates in the Poor Law institutions do not seem to bear any exact relation to legitimacy or illegitimacy. Taking particular ages or particular districts, the death-rate among illegitimate infants is sometimes below and sometimes above that for legitimate children. . . . The variations in this respect as between the different ages, whether in London or elsewhere, are apparently quite without connexion with legitimacy. It would seem as if the protection and food enjoyed by the infants in the workhouse, legitimate and illegitimate alike, removed the presumption against the survival of illegitimate infants.

Certain further considerations are mentioned which begin to give some idea of the cause of this high mortality.

Equally interesting is it to notice that the excess of infantile mortality in the Poor Law institutions is actually greater at the ages between 1 and 6 months than during the first month of life. Whatever allowance should be made for the fact that the Poor Law institutions received many cases in which the mother has been exposed to adverse conditions, it is impossible to avoid the conclusion that the arrangements of the workhouse nurseries—to which Dr. Fuller so pointedly drew our attention—need serious examination.

This inference seems to receive some confirmation from the fact that the excessive infantile mortality in the Poor Law institutions is not universal; and that some have apparently a much higher death-rate than others. We do not wish to attribute too much importance to the statistics of particular institutions for so short a period as one year; but it cannot be right that there should be workhouses in which 40 per cent. of the babies die within the first year. We find that out of the 425 infants born in 10 workhouses (having each not fewer than 20 births in the year) there were only 14 deaths in the year, or 3 per cent., whereas out of the 333 infants born in 10 other workhouses (having each not fewer than 20 births in the year) there were as many as 114 deaths, or 33 per cent., we think it is high time for systematic inquiry.

Personal inspection of certain workhouses served to emphasize these remarks. In some unions the conditions can be fairly described as very good; in others the conditions are not such as would be tolerated under any effective system of supervision.

If the children succeed in passing the first twenty-one days of life, the conditions under which they are placed become in too many instances worse instead of better.

We regret to report that these workhouse nurseries are, in a large number of cases—alike in structural arrangements, equipment, organization, and staffing—wholly unsuited to the healthy rearing of infants. It is in vain that the Local Government Board has for more than a decade laid it down that: "In every workhouse where there are several children too young to attend school a separate nursery, dry, spacious, light, and well ventilated, should be provided. . . . In no case should the care of young children be entrusted to infirm or weak-minded inmates. . . . Unless young children are placed under responsible supervision they cannot be said to be properly taken care of." The boards of guardians have not obeyed. . . . We have visited many workhouse nurseries in the different parts of the kingdom, and we have found hardly any

can possibly be regarded as satisfactory places in which children should be reared.

Pauper imbeciles cannot be said to be proper guardians for young children, and even paupers who are not imbeciles are not the persons that any one except a Government authority would choose for this purpose. When to this is added the primitive nature of the sanitary appliances, and the usual absence of any quarantine arrangements for infants entering from outside, it is not surprising that epidemic disorders are sometimes officially described as "very troublesome."

And, finally, the report states:

In the great palatial establishments of London and other large towns, we were shocked to discover that the infants in the nursery *seldom or never got into the open air*. We found the nursery frequently in the third or fourth story of a gigantic block, often without balconies, whence the only means of access, even to the workhouse yard, was a lengthy flight of stone steps, down which it was impossible to wheel a baby carriage of any kind. There was no staff of nurses adequate to carrying fifty or sixty infants out for an airing. In some of these workhouses it was frankly admitted that the babies never left their own quarters (and the stench that we have described), and never got into the open air, during the whole period of their residence in the workhouse nursery.

It is not surprising that infants brought up in such surroundings should show a high rate of mortality. This of itself is sufficient to any medical man to indicate the serious loss to the community that follows such arrangements. But if it is necessary to instruct the lay person, to whom the death of infants may seem a small matter, the remarks on p. 777 may be quoted:

"The infantile mortality question," says a high medical expert, "is one, therefore, of extreme importance . . . in regard to the physique of the nation. While thousands perish outright, hundreds of thousands who worry through are injured in the hard struggle for existence, and grow up weaklings, physical and mental degenerates. A high infantile mortality-rate, therefore, denotes a far higher infantile deterioration-rate, and this unwelcome fact must not be lost sight of."

There can, therefore, be no doubt as to the necessity for ending such a state of affairs. The problem of thorough and complete reform is too complicated and difficult to be discussed in an offhand manner. It may be that it is further inquiry will show that it is not possible to herd children in a wholesale manner in any nursery no matter how well managed. But the immediate remedy for the worst of the abuses disclosed is not difficult to find. Medical men do not need to be told that if children are cooped up together, without fresh air, proper food, proper sanitation, and efficient supervision, that the results will be bad. It should not be impossible, pending the radical cure of the present disorders, to bring the local authorities to a sense of their duties even in the face of the obstinately self-satisfied attitude of the boards of guardians and the cheerful optimism of the official stepfather at the Local Government Board.

MEDICAL MEN AND THE LAW OF RATING.

ELSEWHERE we deal with the situation which has arisen at East Ham as a result of the action of the local rating authorities in increasing the valuations of nearly all the houses occupied by medical practitioners in the borough. In view of the importance of the matter to members of the profession, we believe that a brief statement of the principles of the law of rating, so far as they affect the assessment of practitioners' houses, will be of interest at the present time. For a more comprehensive exposition of the law reference may be made to the excellent treatise of Mr. W. C. Ryde on the *Law and Practice of Rating*, to which work we are indebted for many of the statements that appear in this article.

The Union Assessment Committee Act, 1862, provides for the making by the overseers of every parish of a list of rateable hereditaments in the parish, together with the gross estimated rental and the rateable value of each hereditament. By gross estimated rental is meant "the rent at which the hereditament might reasonably be expected to let from year to year, free of all usual tenant's rates and taxes, and tithe commutation rate charge, if

any. . . ." The net annual (or rateable) value is defined by the Parochial Assessments Act, 1836, and is, in effect, the gross estimated rental, less the "probable average annual cost of the repairs, insurance, and other expenses, if any, necessary to maintain" the hereditament "in a state to command such rent."

The amount on which any person is liable to pay rates depends on the rateable value of the property occupied by him, and, therefore, it is of the utmost importance to a ratepayer to see that the rateable value inserted by the overseers in the valuation list is not excessive.

From the above definitions it is manifest that in estimating the rateable value the overseers have to consider the rent at which the property may be expected to let from year to year. They are to have regard not only to the rent which an actual tenant may be paying, but also to the rent which a hypothetical tenant may be expected to be willing to pay. The term "rack rent," which is not found in the Rating Acts but is a convenient expression taken from the Income Tax Acts, will be used in this article to indicate this full or maximum yearly rent which a hypothetical tenant may be expected to be willing to pay. The rent which is actually being paid by a tenant for a short term frequently amounts to a rack rent, and if known to the overseers usually forms the basis of the calculation of rateable value. Actual rent is, however, not necessarily the measure of rateable value, because such rent may have been fixed a considerable time before the making of the rate, and the value of the property may have increased or diminished in the interval, or, for various reasons, as, for instance, a personal relation between lessor or lessee, or the payment of a premium, the rent may never have represented the full letting value of the property. Speaking generally, it may be stated that if a rent payable under a yearly tenancy has been fixed recently, without payment of any fine or premium, such rent is *prima facie*, but not conclusive, evidence of value.

Where there is no tenancy—that is, where a person occupies his own house—the rule for fixing the rateable value is the same, but as no rent is being paid, other evidence has to be relied on. This evidence may take various forms, such as the amount of a previous rent, the price paid for the property, a comparison of the property with similar properties situate in the same neighbourhood, etc. None of these would be conclusive, but they would be factors which might properly be taken into consideration in estimating the rent which the hypothetical tenant might be expected to be willing to pay.

It has been held that property must be valued as it exists at the time when the rate is made, with all the then existing circumstances. This point is very important. In *R. v. Grand Junction Railway Company*, Lord Denman said: "The house must be valued as it stands, a dwelling-house must be valued as such, and not at the higher value which it would possess if converted into a shop; and the supposition of a tenancy is only a mode of ascertaining the existing value to the existing occupier."

The next question for consideration—a question which has been very prominent at East Ham—is whether the houses occupied by professional men, or, for the purposes of this article, by medical practitioners, are to be valued simply as private houses, or are to be assessed as business premises. As a general rule, premises which are used for trade purposes command higher rents than similar buildings which are occupied simply as private houses, the obvious reason being that the profit which a trader expects to make by carrying on his business in a particular building is a factor in determining the amount of rent he can afford to pay. How far, then, is the rateable value of premises to be measured by the amount of profit made by the occupier? Mr. Ryde points out that in no part of the law of rating has there been more confusion than in dealing with this question. "Great part of the difficulty will disappear if it be remembered that the ascertainment of rateable value depends upon the construction of a statutory definition, and that the precise words of that definition must be the sole criterion." Now the definition of rateable value, which has been quoted in this article, makes rent, and not profit, the measure of value. The word "profit" does not appear in the definition, and, therefore, it is clear that rateable value is not measured by profit.

*This statement was actually made by a person of some scientific standing.

It is, however, equally clear that the amount of profit which a tenant expects to make, or, in the case of a continuing tenancy, the amount which he has already made, may affect the rent which he is prepared to give for a house. If the occupation of a particular house is necessary in order to enable him to make, or to continue to make, a given amount of profit, this profit will affect to a very material extent the rent he is willing to pay. If, on the other hand, there are a considerable number of houses almost equally well suited for his purpose, he will be inclined to pay little or no more rent for a particular house than a person who wishes to occupy it merely as a private residence. Mr. Ryde considers that "if the profits depend upon the personal skill of the tenant, and can be made in any other premises quite as well as in the premises in question, then the expected amount of the profits will not affect the rent that tenant will give. But if the profits can be earned only on the premises to be rated, and can be earned there by any ordinary tenant, then the expected amount of the profits will affect, and affect very materially, the rent which a tenant will be willing to give." He submits that the true rule is as follows: "As a matter of law, profits must be regarded as affecting rateable value, just so far as those profits would, as a matter of fact, affect the rent which may reasonably be expected."

The principles laid down in the foregoing statements may now be applied more directly to the assessment of medical practitioners' houses. In valuing these it is clear that the overseers and the Assessment Committee have to apply themselves solely to the question, For what rent may the property be expected to let from year to year in its existing condition? The production of a lease or agreement of recent date showing the actual rent paid is ordinarily the best answer the practitioner can give to this question. If there are no special clauses in the lease, if the value of the property has not altered materially since the rent was fixed, if no premium was paid on the granting of the lease, and if the lessor and lessee were at arm's-length when making the bargain, the rent is a rack rent, and would generally speaking be accepted as representing the gross estimated rental. If these conditions are not present, the rating authorities may properly decline to take the rent as conclusive and may require other evidence of value. But what is the exact bearing of the words "in its existing condition"? It may be argued that in its existing condition the house is a house occupied by a medical practitioner, and therefore that the use to which he puts the house—and, incidentally, the profit he makes therein—are factors to be considered by the rating authorities as affecting the value. This contention—which is the real point at issue at East Ham—admits of a twofold answer. In the first place, the profits of a medical practitioner depend upon his personal skill, and can be made in most houses of a convenient size in a given neighbourhood. It may therefore be asserted with confidence that the profits he expects to make do not materially affect the rent he will give for his house. But, secondly, even if the profits do affect the rent which he is prepared to give to some small but appreciable extent, still the rating authorities have neither cause nor power to go behind the rent, provided always that it is really a rack-rent. Any special value which the particular premises may possess for the purposes of profit-making has had its effect in determining the rent which the practitioner will be willing to pay; that special value, therefore, is included in the rent, and nothing further can be added thereto by reference to possible profits. This, it is submitted, is the state of the existing law. So far as we are aware, there are no reported cases which decide the exact point at issue with regard to a medical practice.

When the rent at which a house may be expected to let from year to year has been determined, the "gross estimated rental," one of the two values to be inserted in the valuation list, has been ascertained. The rateable value, upon which the rates are actually levied, remains to be calculated. This calculation, however, is a relatively simple process. It is made by deducting from the gross estimated rental the "average annual cost of repairs, insurance, etc." It is not the practice of the overseers to enter into an inquiry as to the actual sums spent on repairing a particular property. The deduction is usually

made according to a settled scale, which varies to some extent in different parts of the country. A common allowance is one-sixth of the gross estimated rental for larger houses and one-fifth for smaller properties. In London, the scale of maximum deductions is fixed by statute, and is as follows:

If the gross value is under £20—one-fourth	} Of the gross value.
If the gross value is under £20 and under £40—one-fifth	
If the gross value is £40 and upwards—one-sixth	

Reference must now be made to the procedure under the Rating Acts, and particularly to the method of preferring objections and appeals. The valuation list of a parish outside the metropolis—and the borough of East Ham is outside the metropolis—is corrected from time to time either by revaluing the whole of the property in the parish, or by making a supplemental list containing only new properties and properties which it is deemed necessary to revalue. There are no provisions for compulsory periodical revaluations, and in some rural districts the same valuation has remained in force for many years.

The procedure in making a valuation list, or a supplemental valuation list, is as follows: The list is prepared by the overseers, and is deposited by them for not less than fourteen days with the rate books of the parish for inspection by the ratepayers, public notice of the deposit being given on the church doors. The list is then transmitted to the Assessment Committee (a committee of the guardians of the union in which the parish is situate) who revise it, hear any objections of which notice has been received, and correct the list as may be necessary. If any alterations are made the list is re-deposited with the rate books for further inspection and objections, after which it is again returned to the Assessment Committee, who deal with the further objections and finally approve the list.

As soon as the list is deposited by the overseers every ratepayer has the right to inspect it and to take copies of or extracts from the list. Under Section 18 of the Union Assessment Committee Act, 1862, any person aggrieved is entitled to give notice of his objection, specifying the grounds thereof, within twenty-eight days after notice of deposit has been given. The Union Assessment Committee Amendment Act, 1864, however, empowers a ratepayer to give notice of objection "at any time," and not only within the twenty-eight days just referred to. The objection must be heard by the Assessment Committee at one of the meetings which they are required to hold for hearing objections to the valuation list. The objector need not appear in person, but may be represented by an agent.

If an aggrieved person fails to obtain relief from the Assessment Committee two courses are open to him: (1) He may appeal to special sessions, on giving twenty-one days' notice in writing previous to the sessions and stating the grounds of his appeal, and may appeal thence to quarter sessions. Appeals to special sessions may, however, be made only on the grounds of "inequality, unfairness, or incorrectness in valuation." (2) He may appeal direct to the next practicable quarter sessions on giving notice in writing twenty-one days previous to the commencement of the sessions, and specifying the grounds of appeal. The justices at quarter sessions have power, *inter alia*, to amend the assessment "in such a manner . . . as shall be necessary for giving relief," but they cannot increase the assessment of the person appealing. They may make such order as to costs as shall appear just and reasonable. The justices may give judgement absolutely, or subject to the opinion of the King's Bench Division of the High Court, on a special case to be stated by the sessions. A case is usually asked for during the hearing or immediately after judgement is given, and it is entirely within the discretion of the justices whether to grant it or not. An appeal lies by leave of the Court from the King's Bench Division to the Court of Appeal, and, apparently, thence to the House of Lords.

In connexion with any appeal to quarter sessions in which a point of law is involved, it is usually of importance to the appellant to have accurate information as to the principles on which the rating authority has acted in making or confirming the assessment which is the subject of the appeal. Accordingly, it may be useful to quote the provisions of the Union Assessment Committee Act, 1862,

as to the inspection of the minute books of the Assessment Committee. Section 11 of that Act runs as follows:

The committee shall cause a minute of their proceedings . . . to be duly made from time to time in books to be provided for that purpose, which shall be kept by their clerk under their superintendence . . . and all such books shall at all reasonable times be open to the inspection of every person rated to the relief of the poor in any parish or place in the union, without any fee being demanded for such inspection; and all such persons shall be entitled at all reasonable times to take copies or extracts from the said books, without paying any fee for the same; and if, on request made for that purpose, the clerk of the committee refuse to permit any such person to inspect any such books, or to take copies or extracts therefrom, as aforesaid, such clerk shall for every such offence be liable to a penalty not exceeding five pounds, upon a summary conviction for the same before two justices of the peace.

The system in force within the metropolitan area differs considerably from that applicable to the rest of England and Wales, but can be referred to here only in the briefest manner. Within the metropolis a revaluation of all property is made quinquennially, in accordance with the provisions of the Valuation (Metropolis) Act, 1869. The last revaluation was made in 1905, and the new valuation list came into force on April 1st, 1906. Another revaluation will consequently be made in 1910. The current valuation list is subject to revision in years which are not years of revaluation in case of "alterations in any of the matters stated in the valuation list." The procedure for objections and appeals resembles that applicable to the rest of the country, but differs on points of detail.

The foregoing outline of the law and procedure will be sufficient to convey to the reader a general idea of the measure of liability for rating purposes, and of the course to be followed in order to obtain relief from excessive charges. It should, however, be observed that if an appeal to quarter sessions is determined upon (and sometimes if it is intended to prefer an objection to the Assessment Committee), it is, as a rule, desirable to seek legal assistance.

LITERARY NOTES.

The Walter Scott Publishing Company, Limited, is about to issue a new and enlarged fifth edition of Dr. Albert Moll's work on hypnotism in their "Contemporary Science" Series.

The Oxford University Press has nearly ready *Experimental Embryology*, by J. W. Jenkinson, M.A., D.Sc., Lecturer in Embryology in the University of Oxford. The author deals with the origin of form, and in particular with its origin in the individual. The book is abundantly illustrated.

In connexion with the Poe Centenary, the Oxford University Press is issuing Edgar Allen Poe's Poems and Critical Essays in the Oxford Press series. The volume has been edited by Mr. R. Brimley Johnson, who contributes a life of the poet.

The first number of a new quarterly periodical entitled the *Eugenics Review* will appear on April 15th. It will be published under the auspices of the Eugenics Education Society. The review is said to have for its purpose to give expression to the eugenic movement, to place eugenic thought, when possible, on a strictly scientific basis, and to impress on all classes the dignity, privileges, and duties of parenthood. The society endeavours to secure authoritative treatment of eugenic questions. Its honorary president is Mr. Francis Galton, F.R.S., who initiated the science of eugenics, defined its principles, and started and endowed the Eugenics Laboratory of the University of London. The *Eugenics Review* will comprise amongst other things: (1) Articles by responsible writers. (2) Editorial notes upon such of the topics of the day as illustrate eugenic teaching and demand eugenic comment. (3) Notices of recent books which bear upon eugenics. (4) Official records of the work of the society. The aim of the *Review* will be to make known the results of all seriously-conducted eugenic investigation without bias in favour of any particular school. Its range will include—biology, in so far as it is concerned with heredity and selection; anthropology, in so far as it throws light on questions of race and the institution of marriage; politics, in so far as it bears on parenthood in its relation to civic worth; ethics, in so far as it promotes ideals that lead to the improvement of racial quality; religion, in so far as it

strengthens and sanctifies the sense of eugenic duty. The *Review* will be published at the offices of the society, 6, York Buildings, Adelphi, London.

In the February number of *Travel and Exploration* Dr. C. G. Seligmann relates his experiences among the Veddas of Ceylon, one of the few existing wild peoples of India, who probably represent the remains of the original primitive South Indian stock of short jungle men who led a wandering life. Their attitude towards death is remarkable. Although there is no clearly formulated idea of a death contagion, the rapidity with which all Veddas leave the place where a death has occurred and avoid it for years shows that some evil quality is associated with dissolution. According to most Veddas, the spirit of every dead man, woman, or child becomes a "yaka" (plural "yaku") within a few days after death. Some Veddas, however, say that when ordinary folk die they cease utterly, and that a surviving part, which becomes a yaka, exists only in the case of especially strong, energetic, or skilled men who have shown their strength of character in this world, or who have had the power of calling the yaku during their lifetime. Since each Vedda community consists of a small number of families, usually related by blood and marriage, the yaku of the recent dead—called collectively the Ne Yaku—are supposed to stand towards the surviving members of the group in the light of friends and relatives, and only if neglected will show their disgust and anger by withdrawing their assistance or even becoming actively hostile. Hence, it is generally considered necessary to present an offering to the newly dead, usually within a week or two of death. This offering must consist of cooked rice and cocoanut milk, the food that every Vedda esteems above all others, but betel leaves and areca nuts are often added. In each community there is one man, called "kapurale," or "dugganawa," who has the power and knowledge requisite to call the yaku, and this man calls upon the yaku of the recently dead man to come and take the offering. The yaka comes, and the kapurale becomes possessed by the yaka of the dead man, who speaks through his mouth in hoarse, guttural accents, stating that he approves the offering, and will assist his kinsfolk in hunting, and often definitely indicating the direction in which the next hunting party should go. One or more of the near relatives may also become possessed, but this is not necessary. Soon after the spirit leaves the kapurale the rice is eaten by the assembled folk, usually, but not necessarily, on the spot where the offering was made. This account represents the simplest, and probably a degenerate form of death ceremony, but usually the matter is complicated by the invocation of certain other spirits besides the Ne Yaku.

Messrs. John Wright and Sons, of Bristol, will publish on March 7th, a work entitled *Health Morals and Longevity*, by Drs. George Gresswell and Albert Gresswell, of Louth. In the preface it is stated that the book is put forth merely as a sketch of the important subject dealt with—healthy and vigorous life, how best to ensure and maintain it, a mysterious problem bristling at every point with well-nigh baffling questions. In regard to these the authors have tried to give what may be said on various sides, to throw some additional light, and present some fresh points of view.

In a recent number of the *Archives Provinciales de Chirurgie*, the editor, Dr. Marcel Baudin, gives an extract from a document in the Bibliothèque Nationale of Paris (M.S. fr. 17187, fo. 321), relating to an exploratory laparotomy performed in 1475 on a criminal condemned to be hanged on the gibbet at Montfaucon. He had suffered from pain in the side, stone, colic, *passio iliaca*, etc., and the King's physicians asked permission to open his belly in order to discover the exact state of things. The leave was granted, and the operation is described as follows:

Laquelle ouverture et incision fut faicte et dedans icelluy quis et regardé . . . Et après qu'ilz eurent esté vus fut reconu, et ses entrailles remises dedans. Et fut par l'ordonnance du Roy fait très bien guery, et tellement qu'il, dedans XV jours après, il fut bien guery et eult remission de ses cas, sans despens, et si luy fut donnee avecque argent.

[The which opening and incision were made and the parts within were inspected and looked at . . . And after they had been seen, he was stitched up again and the guts replaced within him. And by order of the King he was very well dressed, so that within fifteen days after, he was well healed, and obtained remission of his sentence, together with a sum of money.]

It is not stated whether the man's consent was asked and a free pardon promised in case he survived, but one may hope this was the case. At any rate, we suppose the physicians would be forgiven by antivivisectionists, as there is no evidence that they made experiments on any animal other than this condemned man.

Medical News.

The Russian Government has decided to establish a new university at Saratoff, and the duty of organizing it has been entrusted to Dr. Rasumowsky, Professor of Surgery at Kasan.

The late Dr. Charles E. Beevor, of London, President of the Neurological Society, left estate of the gross value of £41,439 16s. 2d., of which the net personality was sworn at £41,037 10s. 1d.

We learn from the *British Journal of Nursing* that the Right Hon. R. B. Haldane, Secretary of State for War, will address the International Congress of Nurses, which is to be held in London in July next, on the nurse as patriot.

We regret that from the list of specially-invited guests who were present at the Hunterian Oration delivered at the Royal College of Surgeons of England on February 15th the name of Sir Richard Havelock Charles, K.C.V.O., was inadvertently omitted.

MR. LEONARD MATHESON has been elected president, Mr. A. Clayton Woodhouse and Dr. Edward Bogue (New York) vice-presidents, and Mr. Douglas P. Gabell one of the honorary secretaries, of the Odontological Section of the Royal Society of Medicine.

THE COURT of Appeal, on February 22nd, upheld the decision of Mr. Justice Joyce, given in July last, that the legacy of £25,000 left by the late Mr. Alfred Beit to the Institute of Medical Sciences Fund, University of London, should be repaid to the executors of Mr. Beit.

THE annual debate before the Chelsea Clinical Society will be held at the Chelsea Dispensary, Manor Street, King's Road, S.W., on March 9th and 16th, at 8.30 p.m., the subject selected being the diagnosis and treatment of tuberculous glands in the neck.

At the meeting of the Harveian Society of London to be held at Stafford Rooms, Tichborne Street, W., on Thursday next, at 8.30 p.m., a discussion on the early diagnosis and treatment of cancer of the stomach will be opened by Dr. W. Hale White and Mr. B. G. A. Moynihan.

THE Royal Sanitary Institute offers the Henry Saxon Snell prize for 1909 for an essay on the principles of heating and ventilating public buildings, with descriptive details and illustrations of the best systems. Particulars can be obtained on application to the Secretary, Margaret Street, London, W.

A SESSIONAL meeting of the Royal Sanitary Institute will be held at the Parkes Museum, Margaret Street, London, W., on Wednesday, March 3rd, at 8 p.m., when a discussion will be opened by Dr. D. A. Carruthers on the control of infectious diseases in schools. The chair will be taken by Mr. A. Wynter Blyth.

MESSRS. HARRY W. COX AND CO., 47, Gray's Inn Road, London, W.C., have issued a catalogue of x-ray, electro-therapeutic, and other apparatus. It contains useful notes on interruptors, charging accumulators, and other practical points, and a number of excellent skiagrams of pathological conditions.

THE National League for Physical Education and Improvement has arranged for a course of five lectures to be given on Thursday afternoons, at 3.30 p.m., at 56, Queen's Gate, by kind permission of Lady Samuelson. The first lecture will be given by Dr. F. E. Fremantle on Thursday next, the subject being the medical inspection of school children.

THE Orient Company will open their pleasure cruise season next month with the dispatch of their ss. *Ormus* on a twenty-five days' cruise to Lisbon, Tangier, Palermo, Catara (for Cetinje), Gravosa (for Ragusa), Spalato, Syracuse, Malta, Port Empedocle (for Girgenti). An Easter cruise will be made to Greece, Constantinople, Asia Minor Sicily, Algeria, Gibraltar, and Portugal.

SIR ROBERT BOYCE, F.R.S., Dean of the Liverpool School of Tropical Medicine, has been invited by the Colonial Office to visit the West Indies for the purpose of looking into the present methods of dealing with sickness in those colonies, and recommending what reforms, if any, can be made with a view to promoting the physical welfare of the people in the Caribbean Islands. He will arrive at Barbados on March 2nd.

THE tax on all medicines containing alcohol has been raised by the Hungarian Government.

THE fifth meeting of the Departmental Committee appointed by the Lord President of the Council to consider the working of the Midwives Act was held on Wednesday, February 24th, at the Privy Council Office. Mr. Almeric FitzRoy presiding. The following witnesses attended and gave evidence: Dr. Hugh Woods, on behalf of the London and Counties Medical Protection Society; Miss Amy Hughes, on behalf of Queen Victoria's Jubilee Institution for Nurses; and Sir William J. Sinclair, M.D.

THE annual general meeting of the London Medical Graduates' College and Polyclinic will be held at the College, Chenies Street, on Monday next at 5 p.m. The annual report shows that there was a deficit on the working of the college in 1908, but that it had not been necessary to carry out the proposal to discontinue the college, owing to a generous offer from Sir Jonathan Hutchinson. The report refers with regret to the resignation from the office of medical superintendent by Captain Hayward Pinch, on his appointment to be director of the Radium Institute.

A BILL providing for the establishment of a Children's Bureau in the United States Department of the Interior has been introduced into the House of Representatives. Its duties will be to investigate and report upon all matters pertaining to the welfare of children and child life and especially the questions of infant mortality, the birth-rate, physical degeneracy, orphanage, juvenile delinquencies and juvenile courts, desertion and illegitimacy, dangerous occupations, accidents and diseases of children of the working classes, employment and legislation affecting children in the several States and territories, and such other facts as have a bearing upon the health, efficiency, character, and training of children. The chief of the bureau shall from time to time publish the results of these investigations. He is to be provided with a full staff of assistants, statistical experts, clerks, messengers, and special agents.

THE first annual dinner of the London School of Clinical Medicine was held at the Savoy Hotel, London, under the presidency of Mr. P. A. Nairne, Chairman of the Committee of the Seamen's Hospital Society, on February 19th. The Chairman, in proposing the toast of "The London School of Clinical Medicine," explained in detail how it came about that the Committee of the Seamen's Hospital, Greenwich, considered that it was the duty of the hospital to afford an opportunity to the medical men to continue their professional studies under the most favourable circumstances. It was felt that in doing this work the Committee was entitled to appeal to the public for funds to carry out the scheme. Sir William Bennett, who replied, said that the plan was not a doctors' scheme to benefit doctors, but was instituted for the good of the public, as all post-graduate schemes should be. The addition to the facilities for post-graduate teaching was demanded, for, in spite of the institutions previously established, such facilities were defective. The London School of Clinical Medicine had now been in existence for nearly three years, and had had about 300 students, and, from a financial point of view, was almost paying its own way. The school was not instituted in any way for the purpose of rivaling any other similar institution; in fact, the work of the school might be described as complementary to other teaching centres for post-graduates. Dr. Guthrie Rankin, who proposed the toast of "The Guests," said that the hospital was devoted to the relief of seamen, and that gave the school a special claim upon the sympathies of the public. For that reason also it could be claimed that the school was in some degree a national asset, so that the appeal for public assistance was well founded. Lord Ridley, in replying, said that the school was a value to the profession, and thereby of service to the public. Sir William Church, who also responded, explained that it was impossible for the ordinary medical schools to teach students the kind of work in which post-graduate schools were well fitted to give instruction. The hospitals with medical schools attached were always glad to see their old students visiting them again, but post-graduate schools were now accepted as a necessity in the education of medical men. Sir Malcolm Morris, in proposing the toast of "The Chairman," said that one object of the meeting was to bring before the public the enormous importance of post-graduate teaching from the point of view of the interests of the public, and Mr. Nairne in acknowledging the toast mentioned that though it was quite true that old students were welcomed back to the wards, nevertheless that was not quite the same thing as the instruction they received at a post-graduate school, for it was evident that the post-graduate student at an ordinary medical school was in the nature of things apt to be crowded out.

British Medical Journal.

SATURDAY, FEBRUARY 27TH, 1909.

MEDICAL PRACTITIONERS AND LOCAL RATES.

MEMBERS of the medical profession practising in East Ham are up in arms at what has the appearance of arbitrary action on the part of the local rating authorities. East Ham is one of the less wealthy districts immediately outside the metropolitan area. The financial position of the borough at the present time is distinctly, if not singularly, unfortunate. The rates have already reached a high level, but, as is the case in many other towns, the expenditure for public purposes shows a constant tendency to increase. At the same time, it is stated that property generally is diminishing in value throughout the borough to such an extent that it is becoming increasingly difficult to let houses, even at considerably reduced rents. It is said that there are a large number of unoccupied houses, and that these tend to remain vacant for considerable periods. This appears to have been the state of affairs last autumn, when the borough council had to consider how best to meet the growing demands upon them in the immediate future. Two alternative courses presented themselves. One was to increase still further the rate in the pound of the existing levy, with the knowledge that a public outcry against the high rates was almost certain to be raised. The other was to increase the valuations of certain properties, and in this way to render a given pound rate more productive of revenue. The authorities at East Ham adopted the latter plan, and accordingly a supplemental valuation list was prepared by the overseers in August, and approved by the Assessment Committee in October, 1908.

Now it is obvious that if all classes of property are valued on a common basis, so that the occupier of every rateable subject bears a fair share of the aggregate burden, the effect of a general revaluation is small, as far as the total amount of the rates payable on any particular hereditament is concerned. But if the members of a particular class or profession are singled out for attack, and the assessments upon their houses are raised while those upon other properties are left untouched, the distribution of the total burden is altered, and the action of the authorities calls for the immediate attention of that section of the ratepayers which is adversely affected. The information we have received goes to show that at East Ham the houses of members of the medical profession have been selected for the special attention of the rating authorities, for it is asserted that the valuations of doctors' houses have been raised, while those of other residential premises and of shops in the same streets have been left undisturbed. We understand that there are some forty members of the medical profession practising at East Ham, and that more than three-fourths of these lately received the unpleasant intimation that the ratings on their houses have been increased. The amount of the increase of course varies in different cases, but in some

instances the ratings are said to have been doubled. The importance of the matter, however, is due not to the amount in dispute but to the principle involved. There is no reason to suppose that the houses of medical practitioners have hitherto been generally undervalued, as compared with houses occupied by other classes of the community, and therefore it is difficult to discover any justification for the action of the overseers. In East Ham, as is well known, wealthy residents are conspicuous by their absence, and medical fees in the borough are, on an average, so low as to render the making of more than a very moderate income a practical impossibility. Indeed, the pecuniary reward to be derived from a medical practice in the borough is so extremely moderate compared with the value of the practitioner's services to the community that he may reasonably expect to receive considerate and sympathetic rather than harsh and arbitrary treatment at the hands of the local authorities.

The ostensible reason for the increased valuations is that it is contended that a doctor's house should be valued, not as a private residence, but as a house occupied for business purposes; and it is on this contention that the local members of the profession have joined issue with the rating authorities. The action of the latter may at first sight appear to be not altogether unreasonable, for a medical practitioner does unquestionably carry on his profession in or from his private residence, which may therefore be said to be his place of business. Moreover, in making his income-tax return, he is allowed to deduct from his gross profits the rent or rental value of so much of the premises as is used for professional purposes. Too much stress, however, must not be placed upon this parallel, for, under the Acts relating to another imperial tax—the inhabited house duty—the residences of medical practitioners are charged at the higher rates applicable to private houses, and not at the lower rates levied on shops and other trade premises. The action of the East Ham rating authorities accordingly requires further examination, seeing that a departure from long-standing practice is justified only when made for reasons whose weight and validity are fully established.

We print in another column an article dealing more particularly with the legal aspects of the question. We have there endeavoured to show that the profits which a medical practitioner expects to make in a particular house do not influence materially the rent he is prepared to pay, and we have asserted that, if this be so, his use of the premises for profit-making purposes is not a factor to be considered by the overseers in estimating the rateable value. We are here concerned mainly with more general considerations.

The situation which has arisen at East Ham is undoubtedly serious, and the question at issue is one of considerable importance to the medical profession at large. It is the common belief that the action of the overseers represents the beginning of a movement which has for its object the raising of the valuations of all houses to the doors of which brass plates are affixed. If this be true, architects, solicitors, and all other professions will be affected, as well as many people in more humble circumstances. Moreover, the question may, ere long, be raised in other places than East Ham. If no attempt be made to resist the alteration in the basis of assessment, other boroughs are pretty certain to follow the lead given them, with the result that the valuations of houses

occupied by professional men may be the subject of a general increase throughout the country. The evil would not stop even here. It is well known that the valuations for income tax, Schedule A, and for inhabited house duty are based to a considerable extent on the local assessments, and, therefore, an increase in the Poor Rate valuation would be followed sooner or later by an increase in the King's Taxes. Within the metropolitan area the same valuation is made to serve both for local and for imperial purposes, and an increase in Poor Rate assessment would there be accompanied by an automatic increase in the assessment for King's Taxes.

At East Ham there is a widespread opinion that if the higher valuations are maintained the saleable values of medical practices will be seriously affected. Local feeling is, therefore, strong, and has been thoroughly aroused. Individual members of the profession have objected to the assessments upon their houses, and in some instances they have already succeeded in obtaining redress. It is felt, however, that an organized movement is likely to be of greater and more permanent value than isolated efforts, and a "Medical Reassessment Association" has been formed with a view to concerted action. A number of meetings have been held, and legal advice has been obtained as to the steps which should be taken. Valuations of the houses of which the ratings have been increased have been made by an independent valuer. The aggregate of these valuations is stated to be only a few pounds in excess of the aggregate of the old assessments, and is far below the aggregate of the increased valuations made by the overseers and approved by the Assessment Committee. The result is therefore abundantly to justify medical men in the locality in the course they have determined upon.

A meeting to hear further objections to the valuation list was held at Leytonstone on February 19th, when the valuations of a number of doctors' houses were reduced, to the satisfaction of the applicants. In other cases the relief obtained is considered insufficient, while the hearing of several objections was adjourned to a meeting to be held on March 5th. It does not appear that the principle on which the opposition to the assessments is based was specifically admitted by the Assessment Committee. The different statements which have been made as to the exact lines on which the rating authorities have proceeded in making their valuations are, however, to some extent conflicting, and the Medical Reassessment Association would do well to depute one of its members who is a ratepayer to exercise his statutory right of inspecting the minute books of the Assessment Committee with the view of obtaining full and reliable information on this point.

It is considered likely that a test case will be taken to quarter sessions with a view to the determination of the point at issue. The cost of an unsuccessful appeal to quarter sessions is expected to be between £30 and £40, while, should the appeal succeed, the Assessment Committee would in all probability be ordered to pay the costs of both parties. A guarantee fund sufficient to cover the probable cost of a test case has been raised.

The importance of the principle which is at stake renders it in the highest degree desirable that the case which is to be the subject of the appeal to quarter sessions should be carefully selected, with a view of bringing clearly before the court the exact point at issue. The object should, of course, be not merely to obtain a reduction in the particular assessment on

which the appeal is based, but also to secure a pronouncement that the local authorities have acted on an erroneous principle in making their revaluation. If this point can be established—and a reference to our article on the legal aspects of the question will show that there are good grounds for supposing that it can be established—a victory will be won which will be of lasting service to the medical profession at large. We congratulate the practitioners of East Ham on the public spirit they have shown, and wish them complete success in the fight that lies ahead.

SLEEP AND HYPNOTICS.

THIS, if one may judge from the number of cases of suicide attributed to want of sleep, and from the frequency with which the complaint is heard of sleeplessness in milder forms, is an age of insomnia. It is, we suppose, one of the symptoms of the neurasthenia which is too much with us. We are keenly aware that this explanation explains nothing; indeed, it is a case of *obscurum per obscurius*, for insomnia is a very definite thing, while neurasthenia is a pathological shadow. It is, however, useful for clinical purposes, as the term "Italy" was when Napoleon described it as not a country but a geographical expression. Dr. Farquharson, in the interesting paper which we publish this week, tells in simple language nearly all there is yet to be said about sleep. He thinks, and in our opinion rightly, that the physiological causes of sleep must differ, and he asks for information. Alas! we can find nothing newer than Landois's description of sleep as "the consumption of potential energy in the nerves, principally in the central organs, which renders restitution necessary. Perhaps accumulation of decomposition-products in the body (lactates) induces sleep." This really means that we sleep when we are weary, and carries us little further than Corin's knowledge that "the worse one sickens, the worse at ease he is," and the like elementary facts, which led Touchstone to call him a "natural philosopher."

We are, perhaps, rather in the habit of assuming that everything in this era of light is new, even our diseases. But insomnia, like neurasthenia, and its more formidable congener hysteria, must be almost as old as man. No one has described insomnia better than Shakespeare, who makes King Henry the Fourth, when he cannot lure that sleep "that knits up the ravel'd sleeve of care" to his pillow, exclaim:

How many thousands of my poorest subjects
Are at this hour asleep! O Sleep, O gentle Sleep,
Nature's soft Nurse, how have I frightened thee,
That thou no more wilt weigh my eyelids down
And steep my senses in forgetfulness?
Why rather, Sleep, liest thou in smoking cribs,
Upon uneasy pallets stretching thee
And hush'd with buzzing flies to thy slumber,
Than in the perfum'd chambers of the great
Under the canopies of costly state
And lul'd with sound of sweetest melody.

But after all Dr. Farquharson is, perhaps like most of us, more interested in finding a remedy for the disorder than in discussing its causes and nature. We agree with him that the old advice to count imaginary sheep leaping through a gap and such like devices are of little avail in most cases. Reading is often successful, but the book must be judiciously chosen. It must not be so dull that it cannot be read at all: on the other hand it must not be exciting, or it will murder sleep as effectually as *Machbeth*. Sir Henry

Holland found poetry an admirable soporific; the particular form which served best for the purpose was in his case the sonnet. In other cases the epic is more efficacious. Lecky found comfort in rehearsing poetry which he had learnt by heart; and Döllinger in his old age committed some books of Homer to memory for the same purpose. But what is to be done when none of these things will relieve the maddening monotony of telling the weary footfalls of the hours through a long night? Here we come to a point where opinions and practice will differ, and where even practice may sometimes be divorced from opinion. Sir James Paget says that a person will sleep all the better for a night of wakefulness. But then he tells us that he had only had two sleepless nights in his life—and "he jests at scars that never felt a wound." And what if it be not one night, but several in succession with days of heavy work between?

Dr. Farguharson does not shirk the thorny question of hypnotics, and he frankly gives us his own experience. Modern science has placed in the hands of the physician a large number of sleep-compelling drugs, the effects of which have been carefully observed. A summary of recent work on this subject may be useful.

At the invitation of the Berlin Medical Association. Professors Thoms and Ziehen not long ago read papers on modern hypnotics, the former treating the subject from the standpoint of the pharmaceutical expert, and the latter from that of the clinician.¹ Professor Thoms stated that the study of chemical constitution and physiological action has materially advanced our knowledge in regard to hypnotics, and the continued study in this direction, controlled by clinical results, must bear good fruit. Brunton, he said, gives as the essentials for the onset of sleep: (1) That the flow of blood to the brain must be checked as much as possible, which can be attained either by deflecting the blood from this organ or by quieting the activity of the heart; and (2) that the functional activity of the brain must be diminished. It is well known that stimulating medicaments increase the blood pressure, whereas it is diminished by narcotics. Hans Meyer pointed out a curious fact relative to chemical substances which induce sleep. Narcotic substances are fat solvents, and experiments made by him had led him to the conclusion that all chemically indifferent substances which dissolve fats and fatlike substances must act narcotically on protoplasm. The action will be strongest on those cells, such as nerve cells, in which fatlike substances are contained. The comparative strength of the action of narcotics must be dependent on the mechanical affinity to fat-like substances on the one hand and to the other constituents, such as water, on the other. The coefficient of its distribution between fat and water was therefore proposed as an index of the narcotic activity. In discussing the actual chemical constitution of various hypnotics, he deals first with the group of substances containing one of the halogen elements, of which chloral and its derivative are the chief representatives. Chloral has been shown to owe its action to the reduction compound tri-chlor-ethyl alcohol. This body is paired with glyconic acid, and is excreted in the urine as urochloric acid. An important division of this group is found in the halogen acid amides. Neuronal (di-ethyl-bromine-acetamide) and bromural (mono-

bromine iso-valerianyl urea) probably owe their hypnotic action to the hydroxyl groups, though the bromine in both undoubtedly exercises a sedative effect. The second group consists of those narcotics whose hypnotic action is supposed to depend on an alkyl group; of these the first is ethyl alcohol, which is only hypnotic in large doses. Amylen hydrate (tertiary amyl alcohol) is the most interesting of this group, as it belongs to a series of methyl carbonol compounds. The tri-methyl carbonol is twice as weak as the dimethyl-ethyl carbonol or amylene hydrate, while the tri-ethyl carbonol has a still more powerful hypnotic effect. The next subdivision consists of the methan derivatives of the sulphones, and is represented by sulphonal, trional, and tetronal. Applying Meyer's theory to these compounds, it is found that the coefficient of trional is 4.46, that of tetronal 4.04, and that of sulphonal only 1.59. As a matter of fact, this proportion is approximately that of the hypnotic activity of the three substances. The third subdivision is that of the substituted carbonic acid amides. Urethan and hedonal owe their action, no doubt, to ethyl groups. The urea derivatives also come into this group, and of these di-ethyl malonyl urea (veronal) is a stronger hypnotic than the corresponding methyl compound, while in this group the maximum hypnotic activity appears to be possessed by the di-propyl compound which goes by the name of "propanol." The third great group consists of the aldehydes and ketones, of which paraldehyde and acetophenon (hypnon) are representatives. In these, again, the ethyl group plays an important part.

Professor Ziehen discussed the subject from a totally different standpoint. Regarding chemical medicaments as one means of inducing sleep in patients suffering from nervous affections, he analysed the conditions calling for the application of special drugs. He said that in certain cases of mild sleeplessness, sedatives were the best hypnotics, while in more severe disturbances, the selection of the proper drug must be determined by a consideration of several circumstances. Bromine given in the form of sodium bromide in doses of 30 grains for several days might eventually yield satisfactory results, and though it was necessary to exercise the virtue of patience, the feeling of safety often more than counterbalanced the slowness with which the effect was produced. In neurasthenia, especially when there was marked excitability, it was necessary to employ a stronger drug, and under these circumstances the choice lay between neuronal and bromural. The former acted more strongly than was accounted for by its bromine content. The ordinary dose of 15 grains might be increased safely up to 22½ grains. It did not seem to produce unpleasant subsidiary effects, a habit was not easily induced, and the drug did not readily lose its power. Bromural, the dose of which for an adult was 10 grains, was useful and its administration was rarely accompanied by disturbing secondary effects, and was particularly valuable in children. In neurasthenic insomnia the valerian preparations also were at times useful; hyoscin and duboisin acted promptly and powerfully when there was marked motor excitability, but neither was always well tolerated, and it is necessary to exercise care and to continue their use only in cases in which they proved to act well.

In spite of the great chemical difference between them, amylen hydrate and paraldehyde acted very similarly. Both were useful in practically all forms of sleeplessness. They acted rapidly, but the effect

¹Deut. med. Woch., April 2nd, 1908.

soon passed off, so that their chief value was in cases of nervous sleeplessness in which a prompt action was desired, and a delayed action would be likely to distress the patient. The dose of each was 40 to 60 grains. Both were certain in their action and practically free from danger, for, although he had used them largely, he had never met with any toxic effects. In one case a patient took 20 grams of paraldehyde by mistake (about 5 drachms), and awoke after eighteen hours' deep sleep, without having presented any threatening symptoms. Ziehen considered that chloral should be expunged from the list of hypnotics, its only advantage being its cheapness. Chloralamide was more useful; it did not act so well as veronal or trional, but was less dangerous, and did not engender a habit. He gave it in doses of from 45 to 60 grains. Isopral, though a very active drug, acting rapidly, was dangerous, as it had an injurious effect on the heart. Chloretone was a homologue of isopral, but Ziehen said that his experience with it was too limited to justify him in forming an opinion as to its value. Dormiol, on the other hand, was practically without bad effect on the heart, and was a good hypnotic, which might, he thought, well be used in alternation with other hypnotics. With regard to the group consisting of sulphonal, tetronal, and trional, Ziehen expressed the opinion that the two first named might be neglected, since sulphonal frequently produced serious subsidiary symptoms, and tetronal also was too dangerous for ordinary use. Trional produced a prolonged sleep, but the action often took a considerable time to develop; the plan of giving the drug some two or three hours before the sleep is desired might be successful, but as the interval between the taking of the drug and the falling to sleep varied even in the same individual, this method was impracticable. The dangers associated with the exhibition of trional were comparatively slight. It had no undesirable action on the heart. Haematoporphyria and similar results which had been observed could be avoided by careful dosage. The combination of trional with paraldehyde, recommended by Pouchet, had great advantages, for the doses could be materially diminished, and the sleep, in response to the paraldehyde, set in rapidly and, thanks to the trional, lasted long. Ziehen next dealt at length with veronal, expressing himself as being very sceptical about the dangers of this drug, though admitting that unpleasant secondary effects were not uncommon. He usually gave $7\frac{1}{2}$ grains to start with, and increased the dose, if necessary, to 15 or 22 $\frac{1}{2}$ grains if the drug were well tolerated. Its action, however, might be delayed for a considerable time, amounting even to several hours, and, unlike trional, the delay could not be prevented by combining it with other hypnotics. Veronal often lost its power after it had been given for a time. He pointed out that when this had taken place, it was found that trional no longer acted well, and similarly when trional lost its effect, veronal no longer acted well. With regard to the urethan group, he said that he had not convinced himself of the therapeutic value of urethan itself, while bedonal given in doses of from $7\frac{1}{2}$ grains, rising to 30 or even 45 grains, was useful at times. It was not so good a hypnotic as veronal or trional, but it did not lose its effect readily, and was more or less free from secondary consequences. Propanal had a more prompt action than veronal, was quite reliable and did not, like veronal, produce drowsiness during the day following

the dose. Its chief disadvantage—a very serious one—was the narrow margin between a therapeutic and toxic dose; to give $7\frac{1}{2}$ grains was to approach the danger zone, while from 5 to 6 grains was the hypnotic dose. Hypnone, according to Ziehen, had not proved useful, but he thought it still too early to speak positively about hypnal, viferral and some others.

THE NEW ROYAL COMMISSION ON UNIVERSITY EDUCATION IN LONDON.

THE new Royal Commission on University Education in London has before it a task which will put to the test the statesmanship even of its most distinguished members. The Commission is to inquire into the working of the present organization of the University of London, and into the facilities which already exist in London for advanced education—general, professional, and technical—and to consider what provision ought to exist in London for university teaching and research. It is to make recommendations as to the relations which should exist between the university, its incorporated colleges, the Imperial College of Science and Technology, and other schools and public bodies concerned, and to recommend the necessary changes in constitution and organization.¹

To no department of higher education in London ought the results of the inquiry to be more important than to medicine. There are very many matters affecting medical education, and the relation of the medical schools to the university, which require adjustment. They may be summarized in two general propositions: first, that the university should be so constituted that it shall stand in such relation to the medical schools, and shall conduct its examinations in such a manner as to attract at least the large majority of medical students in London to become undergraduates; and secondly, that it should be in a position to maintain or encourage advanced medical education and research. When the Senate, as we announced some months ago, expressed the desire that a Royal Commission should be appointed, the medical schools of London addressed a joint letter to the Prime Minister asking specifically that the Commission should deal with medical education. This letter pointed out that of those medical students who took the whole of their professional course in London, less than 30 per cent. were undergraduates of the university; that in no other university town did the great body of medical students remain outside the university; and that in London they so remained, not because they did not want a degree, but owing solely to the difficulties which the university put in their way. We venture to say, as we have said before, that these difficulties do not arise with regard to the medical curriculum proper; they are not due to special exactions with regard to medicine, surgery, and midwifery, or pathology, nor to any unreasonable difficulty in the examinations in these subjects. They arise at an earlier stage, and are due more especially to the character of the matriculation examination, which is essentially inappropriate, since it should be the object of matriculation to ascertain whether the candidate has had a sufficient grounding in general principles and is possessed of sufficient natural intelligence to benefit by the instruction which it ought to be the duty of the university to give. As it

¹ The full terms of reference are given at page 574.

is, the regulations of the matriculation examination are founded on a wrong principle, are badly conceived, and are still more badly carried out. By a large proportion, if not by the majority of those who pass the examination, it is looked upon as an end in itself—as a certificate entitling them immediately to proceed to earn their living as school teachers or in other capacities. It is true that the university accepts a large number of other examinations in lieu of its own matriculation; but this is an admission of failure, and the University of London cannot afford to continue to fail.

The second point—the encouragement of higher scientific studies and original research—is very largely a question of endowment, and we venture to believe that if the university improve its constitution it will not fail to attract benefactions. The pious founder is still with us, but he is not attracted by a body which has not yet achieved a condition of stable equilibrium.

The composition of the Commission has, perhaps, been affected by the circumstance that the original object with which its appointment was proposed was to inquire into the relations of the university to the Imperial College of Science and Technology. This may perhaps account for the absence from the list of any representative of medicine, or, indeed, of the biological sciences, unless exception is to be made for the distinguished Chairman, whose philosophical studies may perhaps entitle him to that designation. The Medical Faculty has been, from the beginning of the university, numerically the most important, and until the Imperial College of Science and Technology is incorporated into the university, when it will have at least a worthy rival, it will remain the most distinguished and the most renowned. We regret, therefore, that no representative of medicine finds a place on the Commission; at the same time, it must be confessed that it would be difficult to find any such representative in London who was not more or less committed to a particular view, or who might not be thought to be so committed by those of an opposite school of thought. It would not perhaps have been easy, but it would not, we believe, have been impossible to have found some member of the profession not directly connected with London whose impartiality would have commanded respect, and whose technical knowledge would have been of great advantage to the Commissioners in sifting the evidence which they are to hear, and in drafting recommendations which it is to be hoped will at length fairly launch the university on a career which shall be as generally useful to the cause of higher education, both general and professional, as its best friends could wish.

THE PROFITABLE "PROPRIETARY."

THE prospectus which lies before us of a limited liability company, newly formed with a capital of £100,000 to develop the sale of certain proprietary medicines, furnishes an illustration of the profitable use which the owners of such preparations make of the fact that the public loves to dose itself. In this prospectus it is stated that "among the numerous patent medicines which have made fortunes for their owners may be mentioned 'Pink Pills,' the proprietor of which left about £1,600,000, though he had advertised the remedy extensively for only about sixteen years, while the

owners of Beecham's Pills and Holloway's Pills, though widely known for their generous benefactions during life, gave or bequeathed enormous fortunes"; and, as regards the company now formed, "without giving full expression to their expectations, the directors confidently predict that the profits will be sufficient to pay handsome dividends, beginning with from fifteen per cent. to twenty per cent. the first year, and rapidly rising." The proprietary articles which are to be taken over are five in number, consisting of "Capsuloids," "Mother's Advice" (formerly called Cicfa), "Haemogalloles," "Figuroids," and "Sciaticine." An analysis of Capsuloids was published in the BRITISH MEDICAL JOURNAL of April 4th, 1908, page 833, which showed the principal constituent of this preparation for the hair to be haemoglobin. "Mother's Advice" formerly called "Cicfa," and before that known as "Tablones," figured under the latter name in trade-mark litigation in 1906, and was then stated in court to contain pepsin, diastase, and other ingredients. Figuroids appeared among other nostrums for obesity in an article in the BRITISH MEDICAL JOURNAL, November 21st, 1908, page 1566, and the analysis there given showed its principal constituents to be phenolphthalein and hexamethylene-tetramine. Sciaticine and Haemogalloles appear to be new, and both of them are stated to have received much medical support; it is not necessary to comment on the latter statement. The excellence and merit of all the preparations are, of course, vaunted in the prospectus: but no uncertainty is shown as to the part played by advertising in making the sales. An accountant's certificate is reproduced showing that the Capsuloid Company and the Figuroid Company have together spent £101,000 in advertising in five years, and have in the same time made a net profit of £52,500. No doubt the promoters of the new company are justified in saying: "It is evident that such increased advertising as is made possible by 'the additional capital will result in an enormous increase in business'; but the further statement may be doubted: 'In these days of increasing intelligence on the part of the public the continued success of any remedy is largely dependent upon its merit,' success being, of course, taken to mean commercial success, and not curative efficacy."

THE COMING CHANGE IN THE MEDICAL PROFESSION.

AN address on The Coming Change in the Medical Profession, recently delivered by President Charles W. Eliot, of Harvard, is published in the *Boston Medical and Surgical Journal* of February 11th. After speaking of the great advances in medical science during the past half-century, he went on to ask if it was possible to foresee in any measure the changes in practice of medicine as a money-earning and livelihood-yielding profession which these advances would bring about. He said he had heard that medical practice had been rather seriously affected in many of the large cities of the United States by the increased attention—"often an ignorant, crude attention"—given to the relation of the mind to the body. He heard, too, of serious reduction of fees resulting from the widespread mastery of the various exquisite skills involved in surgical practice to-day. He was persuaded that many of the operations which used to be regarded as justifying high fees were now often performed for low ones, and that this tendency had not yet exhausted itself. He added that the great scientific powers which had been brought to bear on preventive medicine would strongly affect private medical practice as a

means of livelihood and the prospects of the profession as a whole. President Eliot went on to ask: "Must we not therefore give a new attention to preventive medicine as the stronghold of the medical profession hereafter? We see signs of it already developing a considerable capacity of earning a livelihood, and that capacity is necessarily at the root of every liberal profession, as of every trade. It is good to see how the salaried places are multiplying in preventive medicine, and how good the salaries have come to be in many of our cities, and they are better still in Europe." He proceeded to say that the practice of medicine would be seriously affected if preventive medicine becomes successful on a broad scale. "The very source of the livelihood," he said, "will be dried up if preventive medicine succeeds. We might perhaps imagine that surgery would on the whole escape from this result of the well-directed expenditures of society for protection against disease, and that surgery would remain a better field for the acquisition of a livelihood than medicine." But even that, he thought, might be doubted, because almost all the discoveries in bacteriology and pathology and other contributory sciences tended to prevent the internal injuries and disorders for which surgery now so often supplied a remedy. Not even the surgeon, in President Eliot's opinion, can rely on private practice fifty years hence as the means of yielding the livelihood that it yields now, and as a means of livelihood surgery has already been somewhat impaired. Inspired, apparently, by the dismal outlook which he sees for surgery, the orator suddenly asks: "Shall we not welcome the coming change? Is not the function of the medical profession regarded as preventive, higher, better, happier than the function of the medical and surgical profession regarded as curative?" One great consolation he offers us in regard to the future of the profession: we have a great deal of truth still to learn and to acquire, and we may well be grateful for that prospect. This is about the only thing in this distinguished layman's address which seems to afford to doctors matter for gratitude. There are several points in his address which calls for comment, but we need only mention one. It is doubtless true that the medicine of the future will be to a large extent preventive. But we should like to hear something more definite about those "good" salaries which are paid to the guardians of the public health. We confess we do not look for them in more than a few places in our own country, and we see no hint of them even in the Minority Report of the Royal Poor Law Commission, the recommendations of which, as far as they affect doctors, may be summed up as the apotheosis of the medical officer of health. President Eliot has evidently a high opinion of the self-sacrifice of the medical profession, but he does not put the case strongly enough. He does not point out the remarkable fact that the progress in science which is to change the healing art into preventive science has been the work of the doctors themselves. The fact was surely remarkable enough to deserve mention, for it is the one example of a profession striving to abolish the reason for its own existence and to dry up the sources from which it draws its livelihood. And what is its reward? Hatred and all uncharitableness on the part of fanatics who, if they could, would stop all progress; carefully measured encouragement from the State and from public bodies, and indifference from the people at large, who, owing to the extinction of the scourges from which they have been delivered, cannot appreciate what has been done for their welfare.

NEWSPAPERS AND CANCER CURES.

OVER and over again we have pointed out the immeasurable harm that is done by the publication, in sensational form, by newspapers of statements as to "cures" for cancer, consumption, and other diseases. No editorial censorship seems to be exercised in such matters; with one or two honourable exceptions, the papers appear to act on the principle that in matters medical any unsifted rubbish is good enough for their readers; and it must be owned that the public which reads these accounts of marvellous cures is only too eager to be deceived. As far as the ordinary person, who is well himself and "bath no friend or brother in the fray," is concerned, one might say *decipiat*. This readiness to swallow whatever is put into his mouth by ignorant and irresponsible scribblers will doubtless continue until, possibly three or four centuries hence, the diffusion of scientific knowledge has created an intellectual atmosphere wherein belief in such things cannot live. In the meantime it is the duty of the medical profession to keep on protesting against the hideous cruelty of raising false hopes of cure by statements made, like the razors of which Peter Pindar sings, to sell. It is not only cruel but dishonest, for it is aiding in the diffusion of falsehood. This would be bad enough if the untruth were of the speculative order; but the announcement of illusory cures must always have the most disastrous practical effects. A recent example of this evil is to be found in the case of Dr. W. T. Bull of New York. That distinguished surgeon, whose death we regret to see reported, was said, a short time ago, with the greatest positiveness to have been cured of a cancer in the throat. The American newspapers, of course, eagerly seized on the opportunity for a "boom," and their statements were considered of sufficient importance to be telegraphed to leading newspapers in this country. Yet the true state of the case must have been known at least in New York nearly a month before his death, for on January 27th the following bulletin was issued by his medical attendants: "Owing to the continued erroneous and misleading reports concerning Dr. Bull in certain newspaper articles and to the fact that these reports are arousing false hopes in the minds of many sufferers from cancer throughout the country, it seems wise to issue the following statement: "Dr. Bull's general condition and the rheumatic complications have improved sufficiently to warrant his departure for the warmer climate of Savannah in the near future. The original growth which was the real cause of his illness has never been cured." Nevertheless, we saw no contradiction of these "erroneous and misleading reports" till after his death. It is a too familiar story. Some temporary improvement of health takes place, and this is forthwith trumpeted to the world as a cure. It is natural that, the wish being father to the thought, any arrest, however passing, in the development of a cancer, and any relief from complications, whether dependent on it or accidental, should be hailed by the patient and his friends as warranting the hope of recovery. All doctors know that these things may happen without influencing the final issue of the case. It is important that the public also should understand that improvement in the general health for a time is often unconnected with the local disease, and that the cancer itself is liable to fluctuations in its outward and visible signs, which may deceive the inexperienced. In rare cases the disease may die a natural death, and to the elucidation of this process research is now being directed. We are inclined to think that

in that line of inquiry lies the hidden path which ultimately will lead to the solution of the mystery which still hangs around the disease.

THE UTERUS AND INGUINAL HERNIA.

INGUINAL HYSTEROCLE (the presence of the uterus in the sac of an inguinal hernia) is rare, but is of interest to the surgeon on account of its relatively frequent association with hermaphroditism. The ovary and Fallopian tube have often been discovered in an inguinal hernia, and many surgeons have diagnosed ovarian hernia before operation. In hysterocle strangulation is rare, as the neck of the sac is never very narrow. A valuable monograph on inguinal hysterocle, including a useful epitome of reported cases, has been published¹ by Dr. D. J. Cranwell, Professor of Clinical Surgery at Buenos Aires, in a case which occurred in his own practice. The patient was an Italian emigrant of weak intellect. The hernia had been observed for seven months. Three days before the operation symptoms of incarceration developed, and a hard irreducible tumour was detected in the left groin. A thick cord ran from the tumour into the inguinal canal. The operator's knife laid open an inguinal sac, which contained a deep red, doughy mass. It proved to be a haematoma in the broad ligament, and when drawn out of the sac was found to be attached to an infantile uterus, the thick cord running into the inguinal canal being the cervix. This was divided and the uterus removed. The corresponding Fallopian tube and ovary, both ill-developed, were attached to the uterus, but apparently the right appendages were absent. As the patient recovered, and as the abdominal cavity was not opened during the operation, the precise extent of malformation of the uterus and appendages was not determined. The vagina was a blind sac, 2 in. long. Cranwell has collected reports of 2 cases of femoral hysterocle, 1 of obturator, and 2 of umbilical hernia of the kind under consideration. As many as 45 cases of inguinal hysterocle have now been reported; 31 were without doubt congenital. Malformation of the uterus was markedly frequent, and may have been occasionally overlooked for the reason explained above. In 3 there was double inguinal hernia, each sac bearing a more or less ill-developed uterine cornu. The frequency of hermaphroditic conditions is astonishing. Klotz's patient, aged 24, a reputed male, had hypospadias and two scrotal sacs. One sac held a cystic ovary, a Fallopian tube and part of a uterine cornu; in the other sac lay a testis and epididymis. In 5 cases the patients were to all external appearances males, and the author adds a sixth case published when his monograph was already on its way to the printers, Cornil and Brossard being the reporters.² Kellock's case³ is included in the series, and we can add a seventh example of hermaphroditism associated with inguinal hysterocle, recently reported by Arnolds of Dusseldorf.⁴ Inguinal hysterocle is often congenital, and it is in this variety that hermaphroditism is so often detected. Acquired inguinal hysterocle is mostly found in multiparae, and may be primary like a hernia of the caecum, or may follow an ovary already in the sac. In 9 cases of inguinal hysterocle the uterus was gravid, usually in association with an old enterocle. Hysterocle is rarely reducible, as the uterus, like the caecum, is seldom entirely invested by the peritoneum involved in the sac. Strangulation was observed in only 5 of the 45 cases of inguinal

hysterocle, whilst Lejars noted this grave complication in as many as 5 out of 9 instances of ovarian and tubal hernia. The symptoms of hysterocle are not uniform, as the uterus is so often malformed or not completely involved in the hernia. It is also true that during sexual life characteristic and periodic pains are the rule, but they are absent when the malformation is great or the patient old. A hysterocle in the groin never fails to cause discomfort greater than is experienced by patients with inguinal hernia of a commoner type, and a truss cannot be tolerated. Diagnosis is often very difficult, and, especially when strangulated, an inguinal hysterocle is often supposed to be an epiplocele. A radical operation is always necessary, as a hysterocle causes much distress, and exposes the patient to great peril from strangulation or from a present or future pregnancy. When gestation is present the surgeon may wait until term if there be no severe symptoms. The uterus does not always lie entirely in the inguinal sac; in one instance the herniated segment contained the placenta and the legs of the fetus only (Nores): the patient died two hours after spontaneous delivery through the vagina. Scanzoni induced abortion with good results in his case; spontaneous delivery occurred in Rosanoff's patient, the uterus was then reduced, but removed eleven weeks later; the patient had borne eleven children. In 5 cases Caesarean section was performed, four of the children but only one mother being saved. All these operations, however, were done before the days of thorough aseptic operating. In inguinal hysterocle, where the herniated uterus is not pregnant, the surgeon will still, as a rule, find hysterectomy the only safe course, the hernial gap being treated by a radical operation.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

IN THE BRITISH MEDICAL JOURNAL of February 20th, p. 493, we ventured to give a gentle hint to educational authorities that it would be well for their officials to exercise a reasonable amount of discretion in regard to the use which they make of the reports of their medical officers. We pointed the moral by quoting a letter addressed to a parent not long ago by an education official of the London County Council. In that letter, what purported to be an extract from a report stating the results of the medical examination of a child was given. The extract represented the opinion of a specialist on a case of ear disease, and was, of course, expressed in technical language, which would naturally convey little meaning to an ignorant parent, and would therefore be all the more likely to cause alarm. Moreover, the specialist had thought fit to reflect on the handiwork of a surgeon who had previously operated on the child. This may be right enough if the document had been treated as confidential; our point is that the conveyance of such a report to a parent is wrong from every point of view. We are glad to learn that our remarks have had an immediate effect. At a meeting of the London County Council held on February 23rd, Dr. Beaton referred to the matter and asked the Chairman of the Education Committee whether he would see that in future letters from the medical department should be written so that they might be easily understood by the parents of the child and free from unfair criticism of members of the medical profession. Mr. Cyril Jackson replied that in his opinion the letter ought not to have been sent, and he would endeavour to see that such letters were not sent out again. In this case it was written by a clerk without check by a superior officer, and the clerk had since left the service of the Council. This explanation

¹ *Revue de Gynéc. et de Chirurg. Abdom.*, vol. xii, 1908. September-October, p. 777.

² *Ibid.*, March-April, 1908, p. 135.

³ BRITISH MEDICAL JOURNAL, March 21st, 1908.

⁴ Report of the Niederrheinische-westfälische Gesellschaft für Gynäkologie, *Monatsschr. f. Geb. u. Gyn.*, October, 1908, p. 465.

is satisfactory, as it seems to show that the letter was sent on his own initiative by a clerk. But it is highly desirable, if the machinery of school inspection is to work smoothly, that care should be taken in handling such delicate matters that subordinate officials be not allowed to magnify their office.

TEARS OF BLOOD.

THE belief that certain individuals are able to weep tears of blood is of such antiquity that the German equivalent for "bitter tears" is *blutige Thränen*, "bloody tears." As far, however, as we are aware, no authentic instance has been quoted in which it has been established beyond doubt that the blood was actually secreted by the lacrimal gland. Micas¹ has published a very interesting article, Real and False Tears of Blood. It is a clinical study on conjunctival hæmorrhage. Some years ago the author was consulted about a boy aged 12 years, who from the slightest cause, such as laughing, or sometimes apparently for no cause whatever, wept tears of blood—an occurrence which was often repeated several times a day. The lad was pale and enervated from constant hæmorrhage. The source of the bleeding was the tarsal conjunctiva, which was covered with fine papillae, and light cauterization with the galvano-cautery resulted in a cure. This case led the author to study the literature of the subject. He found that de Wecker was profoundly sceptical as to the existence of real tears of blood, whereas Panas seemed to admit the fact that in certain rare circumstances the lacrimal gland secreted a sanious fluid. George Seyer recorded a case of an infant whose eyes were closed from birth by severe blepharospasm. They were perfectly normal, but when the child cried tears of blood rolled from the lids. A simple collyrium of rose-water cured the condition. Mazars de Layelles reported two cases; one, a delicate anaemic, phthisical girl, began to weep in his presence tears, first blood-stained, and then real tears of blood. Micas cites other similar examples, but, as he says, in none of them is it certain that the blood did not come from the conjunctiva or from the lacrimal passages. He feels that it is unwise to deny the possibility of a sanguineous secretion from the gland, but that examples in which other sources cannot be shown to be present must be exceedingly rare. He divides cases of conjunctival hæmorrhages into subconjunctival and extra-conjunctival. The first, ecchymoses, are in the aged said to be a warning that the arteries are diseased, and that apoplexy may be feared, but Trousseau thought there was little connexion between the two. In 85 cases of subconjunctival ecchymoses in persons over 55 years old which he followed up, only 4 became paralytic, and in one of these the condition of the eye followed a fall. Micas argues that Trousseau was too optimistic, as he himself knows of at least one case where a violent cerebral hæmorrhage carried off an old lady who had had a succession of subconjunctival ecchymoses. The author then discusses extra-conjunctival hæmorrhages, and points out how fatal they may be to babies, giving several instances in which infants have died from the anaemia resulting from bleeding from the eye. Micas finds that protargol is the best drug to use in cases of extra-conjunctival bleeding.

A FURTHER report which has been presented to the General Medical Council by the Committee of Reference in Pharmacy bears testimony to the steady work which is going on for the purpose of embodying

in the next *British Pharmacopœia* the well-sifted results of current research and criticism. The present report is on similar lines to its predecessor published in December, 1906, and includes the results of work down to the end of October, 1908. The report is necessarily concerned mainly with matters of detail, in which the characters and tests to be officially prescribed for drugs and chemicals figure largely; in several cases new monographs are proposed to be substituted for those at present in the *Pharmacopœia*.

WE regret to have to record that Emeritus Professor D. J. Hamilton died on February 19th at his residence in Aberdeen. Professor Hamilton had suffered from a long illness which compelled his resignation last October of the Chair of Pathology in the University, to which he had been appointed in 1882.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

THE Debate on the Address usually occupies a week or more at the beginning of the session, and enables members to discuss certain urgent questions before the real work of the session is entered on. After the address in reply to the King's Speech had been moved and seconded on the first day of the session the debate covered general questions, and some interesting speeches were delivered, notably those by the Prime Minister and Mr. Balfour. On Wednesday the first amendment was moved, namely, that on unemployment, and was opened on behalf of the Labour members by Mr. Barnes. It led to an animated discussion, in which the Government and the Local Government Board were roundly taken to task for not having done more to meet a pressing problem. Mr. John Burns made a spirited defence of his department, and indicated certain directions in which he was prepared to advance. His speech did not satisfy his critics, and after a reply by Mr. Churchill on behalf of the Government a division was taken, and the Government had a majority of 104. On Thursday and Friday the Tariff Reform amendment was debated and rejected, and on Monday Mr. Ponsonby raised the question of the House of Lords and the intentions of the Government. His amendment occupied the whole day, and after closure was defeated by 225 to 47. In the Lords the address was voted last Thursday after two days' debate on the state of Ireland. The same subject occupied the Commons on Tuesday and led to a lively debate which lasted till Wednesday evening. Other amendments on the paper should be disposed of by Thursday night and the Address voted. In this case the Scottish Temperance Bill will occupy Friday as the first private members' day.

Private Members' Bills.—These bills have, as usual, been decided, as to priority of introduction, by the ballot. This year a protest was raised against this system by Mr. R. Pearce, who condemned the present haphazard system for obtaining precedence, and argued that bills on which time had been spent in previous sessions should have a better chance on their reintroduction. He put forward an elaborate plan for the purpose, and Dr. Rutherford supported his proposal. It was opposed, however, by the Chief Whip of the Government, and also by Mr. Balfour and the Prime Minister. In the face of this opposition, the proposal was withdrawn, and the ballot took place as usual. There were 353 members who balloted. The result was to give Mr. Dobson the first place, and, oddly enough, he introduced on Friday the Daylight Saving Bill, which Mr. R. Pearce fathered last year, and fixed the second reading for March 5th. Mr. John Briggs, who drew the next place, introduced a bill to prohibit or regulate the sale of intoxicants on Sundays, and fixed the second reading for March 12th. Mr. Howard, who came third, introduced a bill to amend the law of the repre-

¹ *Recueil d'Ophthalmologie*, November, 1908.

sensation of the people and to remove the electoral disabilities of women. The second reading was fixed for March 19th. Mr. Hills introduced a bill for a minimum wage in certain sweated industries, and fixed March 26th for the second reading. Mr. Dunn devoted his place in the ballot to the amendment of the Education Acts as regards Administration and the Provision of Meals Act of 1906 and named April 23rd for second reading, while Mr. R. Pearce, lucky in spite of his complaint of the ballot, drew seventh place and introduced a bill to amend the Coal Mines (Checkweighers) Act, and selected May 7th for the second reading. Sir Luke White introduced again the Coroners' Bill which nearly passed last year, and Mr. Pirrie, who drew thirteenth place, introduced a temperance bill for Scotland, and selected Friday, February 26th, for the second reading in the hope that the debate on the address might be concluded on the previous day. At the most only eleven Fridays are expected to be available for private members' bills this session, and therefore a large crop of private legislation cannot be anticipated. The bill dealing with unemployment is in the hands of Mr. Hodge and is backed by the Labour Party. It will come on for second reading on April 30th. The Irish members have three bills down, but were not so successful as usual in the ballot. There is one Public Health Bill dealing with water rights in the hands of Mr. Leif Jones, and the second reading is fixed for Friday, April 16th, a speculative date as it is the Friday after Easter, and the House may not have finished the holidays.

Vivisection.—The ballot did not favour the antivivisection members, and so Sir F. Banbury introduced his bill on Monday to prohibit experiments on dogs, commonly called the Dogs Protection Bill. It is backed by Sir F. Channing, Mr. Ellis Griffith, Mr. Swift MacNeill, and Sir Henry Cotton, and is put down for second reading on Friday, May 14th.

Irish Poor Law Reform.—In reply to Captain Craig, Mr. Asquith said it was true that early last year his right hon. friend the Chief Secretary expressed the hope that he would be able to introduce this session a Poor Law Reform Bill for Ireland. But he subsequently suggested that the whole question of Poor Law reform in the United Kingdom generally would have to be considered when the Royal Commission had reported. The report of the Royal Commission, which had now been issued, intimated that a separate report would explain in detail the application of the suggested reforms to Ireland. Until that report had been received and considered in conjunction with the main report, it would not be possible to say whether separate legislation in regard to Ireland would be necessary or desirable. He might add, however, that supporters of Poor Law reform in Ireland need have no apprehension that the recommendations of the Viceregal Commission would be ignored. In reply to a further question, Mr. Asquith said he did not know when this separate report would be issued.

Medical Relief.—Mr. Joynton-Hicks asked the President of the Local Government Board on Monday whether he would issue amended instructions to the pension officers that temporary medical relief, either outdoor or in an infirmary, did not disqualify an applicant for the old-age pension. Mr. Burns said that instructions had already been issued that temporary medical relief should not be a disqualification. He was not aware of any one being disqualified owing to the receipt of such relief.

Legislation for the Feeble-minded.—In answer to Sir George Kekewich, Mr. Gladstone stated on Monday that the question of legislation on the report of the Royal Commission on the Feeble-minded must be subject to Parliamentary exigencies, but he might point out that Section 62 (2) of the Children Act of last session already dealt with feeble-minded children and young persons who were guilty of offences.

Vaccination Exemption.—Mr. Lupton asked the President of the Local Government Board if his attention had been called to the fact that vaccination officers had shown

vaccination exemption declarations to the agents of the trustees of dwellings erected for the public in order that pressure might be brought upon tenants who had made such declarations; and whether he would issue an order directing vaccination officers in future to vouchsafe no information whatever upon the subject of exemption declarations to any persons other than the official superiors of the vaccination officers. Mr. Burns said that he had received a complaint on this subject, and he was making inquiry with regard to it. He might, however, state that under Section 24 of the Vaccination Act, 1867, as amended by Section 6 of the Vaccination Act, 1871, it was the duty of the vaccination officer to allow searches to be made in his Vaccination Register. Any such search would disclose the fact that a statutory declaration had been received by the officer in respect of a child whose name was entered in the register, and in these circumstances it did not appear to him that he could make an order of the kind suggested.

Vaccination in the Navy.—Mr. Lupton asked the First Lord of the Admiralty on Tuesday if a paper written by Surgeon N. Howard Mummary, R.N., was submitted to the Director-General of the Navy Medical Department; if the Director-General sanctioned the reading of the paper at the annual meeting of the British Medical Association last summer; if he was aware that the paper suggested that in the near future all men joining the service should be vaccinated against syphilis with matter obtained through the syphilization of monkeys; and if he would give an assurance that no man on entering the navy should be subjected to voluntary or compulsory syphilization by the surgeons of the navy or others in authority over the men. Mr. McKenna said that he must express his regret that in replying to a previous question in December last from his honourable friend he was unaware that any ground existed for such definite statements as he now made in his present question. On inquiry he found that a lecture was allowed by the Medical Director-General to be read on the subject referred to on the understanding that it represented only the author's own private views. The lecture was not delivered with the authority of the Board of Admiralty, nor was it in any way endorsed by the Medical Department of the Navy. He was making further inquiry into the matter. He could only now add that the suggestion contained in the lecture and complained of by his honourable friend was as repugnant to the Board of Admiralty as it was to himself.

The Housing and Town Planning Bill of the Government has been issued, and may be expected to be put down for second reading on an early day. As it was elaborately discussed in Committee last year, it is hoped that it may pass its second stages in the Commons with rapidity this year. Mr. Hart Davies has given notice that he will raise the subject of the taxation of site values on the second reading.

The Pure Milk Bill.—Mr. Burns informed Mr. Courthope on Monday that he hoped to introduce this Bill early this session, but he could not fix the date at present.

Kissing the Book.—In reply to Sir W. Collins, Mr. Gladstone stated on Tuesday that it was desirable that the form of oath administered in court should in no case require the act of kissing the book. He would consider whether legislation was necessary for this.

At the International Congress on Leprosy which, as already announced, is to be held at Bergen on August 16th to the 19th of the present year, three official languages will be recognized—German, French, and English. The following is the official programme of questions to be discussed: 1. The various clinical forms of leprosy and their diagnosis. 2. The causes and mode of propagation of the disease; pathological anatomy, treatment: the means to be employed by public authorities for checking as quickly as possible the ravages of the disease, and of definitively exterminating it with the least possible inconvenience to those afflicted with leprosy.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

MANCHESTER AND DISTRICT.

OVERCROWDING OF THE PROFESSION.

SINCE the issue of the Educational Number of the BRITISH MEDICAL JOURNAL last summer, the Joint Committee of the Manchester and Salford Divisions has been considering whether some further means might not be adopted to warn young men who might be thinking of entering on a medical career. It appears that some such methods have already been adopted in France where things are, if anything, in a worse condition than in England. A large number of medical associations in France have combined to issue letters of warning, pointing out among other things the large amount of pensions and allowances that have to be made to needy medical men or their widows. In 1891 the Association générale des médecins de France paid out for this purpose 39,490 francs, while in 1903 it was necessary to pay out 170,030 francs. The total sum spent in helping the families of doctors in distress by all the societies in 1904 was 518,000 francs, and the appeals for assistance were constantly increasing. The chief causes of this state of affairs are said to be: (1) The great and uncontrolled increase of illegal medical practice. (2) Overcrowding of the profession itself. In the great centres of population there is one doctor to every 900 inhabitants, while in the rest of the country there is one to every 2,000, the average being for the whole country 10.4 per 10,000. (3) The great increase of clubs, which means a decreasing income for medical men. (4) The lessened amount of illness that exists. In Paris, in 1886, the death-rate was 24.3 per 1,000, and the number of cases of illness was estimated as 243 per 1,000 inhabitants, while in 1904 the death-rate was only 17.6 and the cases of illness 176 per 1,000.

It is further stated that 45 per cent. of the medical men in France do not realize annually £100 in fees. The fact that overcrowding is still on the increase is shown by the fact that while only about 530 medical men fall off the list per year through death or other causes, there are about 1,200 fresh diplomas granted annually. The circular setting forth these facts concludes with an earnest appeal to young men to consider them carefully before embarking on a career that offers so few chances of success in France.

It was felt by the Manchester Divisions that the condition of the profession in England, even if not quite so bad as in France, was sufficiently alarming to justify some similar measures being taken. Accordingly the following circular letter was drawn up, and a copy has been sent to the head masters of all the public schools and the grammar schools in Lancashire, as it was known that many head masters are in the habit of advising their senior boys to take up a medical career:

The Medical Profession as a Career.

February 8th, 1909.

Sir.—We are instructed by the Committee of the Manchester and Salford Divisions of the British Medical Association respectfully to call your attention to the following considerations:

The increase in the number of students this year entering the medical school in Manchester is evidence that there is a complete ignorance on the part of the parents of the economic crisis in the profession of medicine.

In general practice, to which nine-tenths of the entrants are destined, the field of work, and therefore the income, has been contracting, and is bound to contract as disease becomes more and more preventable. A single instance—Dr. Davy, in his presidential address to the British Medical Association, said: "My predecessor told me that fifty years ago his average income from attendance on cases of typhoid was £300 a year. For the past few years my income from that source has hardly averaged 5 guineas."

The BRITISH MEDICAL JOURNAL says: "The average income of the practitioner has been estimated at £200—£250 a year. The chances of being able to save even to the extent of the capital expended in education are in a large proportion of cases slight; while reasonable provision for old age, after family expenses are met, is difficult and too often impossible." This is after a training lasting seven years and costing £1,000—£1,200, and even this pitance is only gained by working seven days a week and being "on duty" twenty-four hours a day, with the natural result that the death-rate in the medical profession is higher than in any other, the army not excepted.

In France and Germany it has been found needful to issue "letters of warning" to intending students, as the results of practice are equally unsatisfactory there.

We would therefore ask you to urge intending entrants to inquire further before joining so overcrowded a profession.

The letter is signed by the Honorary Secretaries of the two Divisions.

THE MIDWIVES ACT IN LANCASHIRE.

At the end of the year 1908 there were 949 midwives on the Lancashire county register, and of these no less than 725 were in bona-fide practice in July, 1901. As 78 of the total are temporarily out of practice, that leaves 871 in actual practice at the end of the year. Some difficulty has been found in getting the midwives to comply with the section of the Act that requires them to give notice in January of their intention to practise, a considerable number each year failing to send in notice. During the quarter ending December 31st 128 stillbirths were recorded, and in 20 cases death of either the mother or the child occurred before the attendance of a medical man. There were 331 cases recorded in which a medical practitioner was sent for in accordance with the rules of the Central Midwives Board, against 263 in the same quarter of 1907. Of these, 143 were for obstructed labour or uterine inertia requiring instrumental assistance, 43 for unusual presentations, and 27 for ruptured perineum. The county has made no provision for the payment of practitioners summoned to the assistance of midwives, and only in very few cases have boards of guardians made any arrangements, mostly extremely unsatisfactory, and limited to purely pauper cases. The circular issued by the Local Government Board in July, 1907, has, in fact, been largely of no effect. Puerperal fever occurred in 42 cases, with 15 deaths, against 36 cases with 19 deaths in the same quarter of 1907, and 21 cases with 10 deaths in 1906. There has thus been a considerable increase in puerperal fever. In 12 instances midwives did not comply with the rules as to forwarding a copy of the record of sending for medical help in cases which subsequently developed into puerperal fever, nor did they report the cases when diagnosed as "fever." In all such cases the midwives are required to answer charges of neglect, while other charges of negligence or misconduct have been made against 3 midwives. The records of sending for medical help have steadily risen in number during the last four years, the numbers being 428 in 1905, 875 in 1906, 1,069 in 1907, and 1,543 in 1908, the increase being due partly to the greater efficiency of inspection, and partly to the midwives realizing more fully their obligations. The two trained nurses appointed to give their whole time to the inspection of midwives report that, though on the whole the records are better kept, and there is a distinct improvement in the mode of practice and in general cleanliness, a certain number of midwives give a considerable amount of trouble by evading the rules, by want of cleanliness and general unsatisfactory conduct; some of the most illiterate hardly seem to have intelligence enough to grasp the present requirements, and through want of education many of them cannot correctly keep their registers. "As a result of continued instruction, some of the midwives who previously had not the faintest knowledge are now able to take the temperature sufficiently well to be able to realize when medical assistance is necessary and a number can already count the pulse." One cannot help thinking that such a report shows a woful defect in the quality of many of the midwives of Lancashire. The Lancashire Education Committee offers annually five scholarships of £30 each for the training of midwives. The proportion of bona-fide midwives compared with the fully certificated is very large, 725 out of 949, and there is some ground for fear that there may be some shortage of midwives after April, 1910. It is said to be possible that attempts may be made to get over this by unqualified women taking cases nominally under the charge of medical men. This is, of course, a dangerous procedure, unless the greatest care is taken, for not only would there be a risk of a charge of employing an unqualified assistant, but unless the oversight by the medical man is actual and not merely nominal, and is strictly and carefully carried out, the lot of parturient women would be no better, if, indeed, it would not be worse, than it is at present.

MANCHESTER ROYAL INFIRMARY.

At the annual meeting of the trustees of the Royal Infirmary, held on February 14th, the Earl of Derby, who was elected president, thanked the meeting for electing him in place of his father, and was pleased to think that he was the fourth member of his family in succession to occupy the position of president. He expressed a confident hope that the King would be able to visit the infirmary when he came to review the Territorial Forces in July.

The Chairman of the Board, Mr. Cobbett, in moving the annual report, drew attention to the serious state of the finances of the infirmary. About £9,000 still remained to be raised in order to open the new building free from debt. In addition to this, the annual expenditure was a matter of great concern. It was calculated last year that by removal into the new building there would be, in the absence of an increased subscription list, an annual deficiency of between £7,000 and £12,000. The subscription list had been increased only to the extent of £1,600, so that the position in which the Board stood was that it might have to spend £10,400, and must spend at least £5,400 more than the income, unless the infirmary was to be carried on in a way which would not give the public the full benefit of its resources. In this condition the Board felt serious anxiety about the future of the institution. Mr. Cobbett, in alluding to the question of women doctors, announced that the Board had considered the question and decided to appoint a committee to inquire into the subject of the appointment of medical women to resident positions in the infirmary and to report in writing to the Board.

Lord Derby said that what the medical women wanted was not remuneration, but experience, and those responsible for the management of the infirmary wished to give them that experience, but they could not do what they had been asked to do on the spur of the moment; he was sure that the wisest course had been taken in appointing a committee to consider the question thoroughly.

PROFESSOR RUTHERFORD AND THE NOBEL PRIZE.

The Council of the Manchester University has shown its appreciation of the achievements of Professor Rutherford by entertaining him to dinner in the Whitworth Hall to celebrate the award to him of the Nobel prize for physics. The Vice-Chancellor, Dr. Hopkinson, was in the chair, and there was a distinguished company to welcome Professor Rutherford, who was accompanied by Mrs. Rutherford. After the loyal toasts had been honoured, the Vice-Chancellor called upon Sir J. J. Thomson to propose the toast of the evening, and reminded those present that Sir J. J. Thomson himself was an old student of Owens College, a governor of the university, himself a winner of the Nobel prize, and the teacher of the guest they were specially met to honour.

Sir J. J. Thomson said that Professor Rutherford owed the Nobel prize to Manchester, for he had already done some remarkable work in physics before he went to Cambridge. He had never really received the recognition he deserved for what he had done in what is now known as wireless telegraphy, for he took with him from Manchester an electrical instrument by which as early as the year 1895 he was able to signal over two miles by means of this wireless telegraphy. At Cambridge he had devoted himself to the investigation of the remarkable properties of gases exposed to the influence of Roentgen rays. He was glad that the Nobel prize had come to Professor Rutherford while still in the full vigour of his faculties, and it would certainly stimulate him to still greater discoveries.

Professor Rutherford, in reply, said he felt honoured by being a member of the staff of the university. He had spent twenty-three years in New Zealand, then passed to Cambridge for three years under Professor Thomson, and then spent eight years in Montreal. As a new arrival in Manchester, his first impression was the strength of its staff not only in the direction of teaching but of research. In no instance had fortune favoured him more than when he was invited to fill the place of Professor Schuster in the Chair of Physics. The history of science showed that it was the professors in the universities that supplied the greater part of the scientific facts. If they took the subject of wireless telegraphy, they found that all the properties of electric waves known to-day were known at Cambridge long before the inventive power of Marconi

brought them to perfection. A complete department of science had been added to our knowledge since 1895, and he felt that the advance of the future would be mainly along the scientific course, and if universities were to hold their place in the national life, they must be the centres of national research.

Professor Rutherford's reticence about his own great achievements was very striking, and at the close of his reply he was accorded a most enthusiastic reception.

NEWCASTLE-UPON-TYNE.

GLASGOW UNIVERSITY CLUB.

LAST week, in the College of Medicine, the annual address to the members of the Glasgow University Club was delivered by Sir Hector C. Cameron, Professor of Clinical Surgery in the University of Glasgow. The subject dealt with was mammary cancer. As the paper is to be published in due course in this JOURNAL the opportunity will be afforded to all of reading it. For the present it is sufficient to say that the address, which bore marks of careful preparation and thought, and which was extremely suggestive, from the point of view of late recurrences of the disease, was listened to by the audience with close attention. Mr. Rutherford Morison, in an able speech, proposed a vote of thanks to the lecturer.

In the evening Sir Hector Cameron was entertained to dinner by the members of the club. On this occasion there was a new departure. Sir Thomas Oliver, in recognition of the knighthood recently conferred upon him, was also a guest. In the absence of the President of the Club, the Rev. Mr. McGonigle, the chair was occupied by the ex-President, Dr. Johnstone Weir, of Jarrow. Between sixty and seventy gentlemen sat down to dinner; among the number were the Lord Mayor and the Sheriff of Newcastle-upon-Tyne and Sir Isambard Owen. In an appropriate speech Dr. Napier Burnett proposed the health of Sir Hector Cameron, who, on rising to respond, was most cordially received. Becoming reminiscent, Sir Hector alluded to the fact that since his student days several of the Chairs in the University had been filled three or four times; but however such events might be a cause of sadness, there was no occasion to be pessimistic, for there was constantly coming on a race of new men capable of filling the vacancies as they arose. To the great advances being made in education Glasgow University was contributing, under the able principalship of Sir Donald MacAlister. Dr. Johnstone Weir, his fellow student, in a delightful speech, proposed the health of Sir Thomas Oliver, who acknowledged the compliment. To Dr. Mearns of Gateshead was entrusted the toast of "Other Universities and Seats of Learning," which was responded to by Sir Isambard Owen in a speech at once racy and full of information.

NEW COLLIERY ACCIDENT STATION.

At the invitation of the owner of the colliery, Mr. Cochran Carr, and in presence of a large number of mine managers and officials, medical men and friends, Sir Thomas Oliver opened an Accident Station at Benwell Colliery. In doing so he alluded to the value of such a station for the reception and treatment of men brought to the surface when injured in the pit, and observed that the early application of the antiseptic treatment to wounds received in coal mines materially shortened the duration of the illness. Sir Thomas paid a high compliment to Dr. G. H. V. Appleby, Surgeon to the Colliery, to whose suggestion as well as to Mr. Carr's generosity the accident station was due. He concluded by expressing the hope that ere long colliery proprietors and mine managers throughout the country would follow the example set them by Benwell Colliery.

MR. HALDANE AT NEWCASTLE.

Mr. Haldane, Secretary for War, in an address to the undergraduates of Armstrong College, made an appeal to the College for officers, and said that his aim was to organize the Territorial Army on scientific lines identically the same as those of the regular army. So far as recruiting for the army of home defence was concerned Newcastle and the northern districts had done remarkably well.

WEST YORKSHIRE.

BRADFORD AND TUBERCULOUS MILK.

THE Medical Officer of Health for Bradford (Dr. Arnold Evans) has issued an interesting report on tuberculous milk and the veterinary inspection of cows, in which he calls the attention of the Health Committee of the Bradford Corporation to the following points: (1) That Bradford milk, probably to the extent of 8 to 10 per cent., may be infected with tuberculosis. (2) That there is considerable danger to human beings from the consumption of this milk. (3) That no direct action other than the application of the regulations under the Dairies, Cowsheds, and Milkshops Order is being taken to abolish this source of human tuberculosis. He suggests that a systematic inspection of all cows in the city should be made and that advice should be given to the owners of infected animals on the importance of separating the tuberculous from the healthy ones. Dr. Evans recommends:

1. That the town clerk be instructed again to advertise the provisions of the model clauses contained in the corporation's local Act of 1900, which has become practically a dead letter.
2. That an arrangement should be made with the Pathological Department of the Leeds University for the examination of milk by the inoculation of guinea-pigs and the provision of a report to the medical officer of health.
3. That the regular inspection of milking animals be made and a veterinary surgeon appointed for the purpose.

These recommendations, if carried out, would certainly tend to lessen the danger from tuberculosis in Bradford, and we trust Dr. Evans will have the support of the Health Committee and the Corporation.

MEDICAL INSPECTION OF SCHOOL CHILDREN IN BRADFORD.

Some reference was made in this column last week to this subject and a hope was expressed that means would soon be found to remove the friction between the medical practitioners and the school medical officers. We are happy to think that a solution of the difficulty is probable. At a meeting of the Bradford Division, held on February 17th, the question was thoroughly threshed out. Dr. Crowley, the Medical Superintendent of the Bradford Education Committee, was present, and very frankly stated his views. He was able to show that the indiscriminate treatment of disease had not been attempted at the school clinic and that there was no intention of doing so. Only the children of very poor parents would be attended to. Children would always be referred in the first instance to their own doctor for medical attendance. The treatment of ringworm and running ears was on a rather different plane. These Dr. Crowley looks on as diseases of a peculiarly dangerous character to the schools themselves and ought to be treated, if necessary, at the school clinic. Certificates that the child was not in a fit state to attend school, if given by a medical practitioner, would be accepted without demur by the Education Authority.

BIRMINGHAM.

ACTION OF THE BIRMINGHAM WATER UPON LEAD.

At the inquiry which is being held in Birmingham with regard to the tinning trade danger and Home Office regulations, Dr. Robertson, M.O.H., said that the soft water with which the city was supplied had an effect upon lead; if a lead-lined kettle filled with the water were allowed to stand on the hob all night, as was common, and then boiled in the morning, the water would contain lead. There would be practically no risk if people would empty their kettles, and if, before using the water in the mornings, they allowed the tap to run a short while. The City Council had memorialized the Home Secretary on the subject, because it was anxious about the number of the common kettles that were being sold in Birmingham.

HEALTH OF BIRMINGHAM.

The death-rate for the year 1908 was 15.9 per 1,000, which is the lowest ever recorded. Comparing the four-yearly period 1905-1908 with previous four-yearly periods at intervals of ten years, it will be seen that there has been a marked improvement in the death-rate:

	Average Death-rate.
1875-1879	24.5
1885-1888	19.8
1895-1898	20.2
1905-1908	16.2

The birth-rate was 28.4 per 1,000, as against 28.3 in 1907 and an average of 31.5 in the ten years preceding 1908.

LIVERPOOL.

PAY WARDS AT THE ROYAL SOUTHERN HOSPITAL.

At the annual meeting of the Royal Southern Hospital, held at the Town Hall on February 8th, a remarkable discussion took place, which has been followed by an animated correspondence in the daily press, and has led to a resolution being passed by the Association of the Honorary Medical Officers of the Liverpool Medical Charities.

At the annual meeting of the hospital Dr. Charles W. Hayward, Operating Surgeon at the Hahnemann Hospital, said he wished to call the attention of the trustees of the hospital to a matter which he thought had not presented itself to them in what he and others conceived to be the true light. There were, he said, at the Southern Hospital one or more private wards into which patients were admitted and treated on payment to the hospital of 2 guineas a week for board and maintenance; but the doctors who attended these cases were not allowed to receive anything for the attendance they gave. These patients, he said, were all, or nearly all, perfectly willing to pay. He quoted an instance in which, he said, the patient was not only able to pay, but had actually arranged to pay a surgeon for an operation, and was about to go into a nursing home, when the friends were advised to send the patient to the hospital, where the operation would be performed for nothing. This was done, to the pecuniary loss of the surgeon who was originally consulted and of the home to which the patient had arranged to go. Dr. Hayward said there were plenty of people who had been in the private wards, several with good names in Liverpool, who were all under the stigma of receiving charity from the medical officer if not from the hospital. Other hospitals in Liverpool had private wards, but their view was that if a patient entered these private wards, it was not fair that the doctor should not be paid if the patient could afford it. He said there was one phrase in the statement of Mr. Adamson, the President, with which he quarrelled, namely, that great care was taken to secure that only the right class of case was admitted. He did not like to use harsh words, but that was not correct.

Mr. Adamson said that the case specially referred to by Dr. Hayward was that of the wife of a ship's officer who in reality was not in a position to pay adequate fees for the operation (amputation of the breast) which was required. He said that the circular, which was sent to every applicant for attendance in the private ward, read as follows:

The private wards at this hospital are for the use of poor persons who can pay 2 guineas per week towards their nursing and maintenance, but who are unable to pay the specialists' fees for the treatment necessary for their cure. Persons who can pay these fees for treatment at home or at a nursing home are not eligible for admission.

Every patient admitted into the private ward was introduced by a member of the honorary staff or by a resident officer by arrangement with an honorary officer. It would be a crying shame, continued Mr. Adamson, if the medical men who used the hospital's theatres and implements, and took up the time of the nurses, should make any charge to the patients. Whenever a vacancy occurred on the honorary staff there was a struggle among medical men to get in. A London man had said the other day that it was worth £10,000 a year to get into a London hospital, and in the case of a Liverpool hospital it must be worth at least £5,000.

In the newspaper correspondence which followed the question was discussed from various points of view. Needless to say, medical practitioners exposed the absurd exaggerations uttered as to the pecuniary value of hospital appointments, and showed that they were sought not so much from their monetary results, but because it was necessary to hold them if men desired to carry out special

lines of clinical work or practice. As regards the question whether adequate means have in the past been taken to limit the use of the pay ward to persons unable to afford fees for operations and other special treatment, it appears that the inquiry form now in use was only adopted on January 4th, 1909. The paying ward has been established since 1892. With regard to the general question of whether honorary medical officers of hospitals should have the right to charge for the services rendered to patients who occupy pay wards and who are in a position to pay professional fees, the Association of Honorary Medical Officers of the Liverpool Medical Charities passed the following resolution at a meeting held at the Medical Institution on February 15th:

That, in the opinion of this association, any honorary medical officers attending patients in hospital who are occupying private wards should be at liberty to charge for their services. That the association does not, however, by this resolution express its approval of the existence of private wards in the general hospitals.

LEEDS.

THE GENERAL INFIRMARY.

An examination of the tables of statistics for the year ending December 31st, 1908, which have been prepared for the annual report, shows that the amount of work done by the various departments remains about the same, and this, as has been pointed out on former occasions, must be taken as an indication that the infirmary with the present number of beds is not capable of dealing with a larger number of patients. The daily number of in-patients during 1908 was 365, as compared with 368 for 1907. During 1908 there were admitted 6,802 patients, which, with 335 remaining in at the end of 1907, shows a total of 7,137 treated during the year, or 51 more than in 1907. The average number of days each patient was resident was practically the same as in the former year, being 18.7 as compared with 18.9. The number of deaths in the infirmary was 531, a percentage of 7.4. Of these, 163 occurred within forty-eight hours of admission, and if these are deducted from the total the percentage falls to 5.2. Of the in-patients 1,240 were admitted into the medical wards and 3,371 into the surgical wards, exclusive of 705 accident cases, and exclusive also of 839 eye cases, 287 ear cases, and 360 gynaecological cases which were admitted into the special wards of these departments.

In the out-patient department an increase of 1,953 in the number of new patients, which reached the large total of 42,371, must raise in the mind of any one acquainted with large hospitals the feeling that a great many patients with trivial ailments and quite able to pay for advice must have attended. In the out-patient maternity department 501 cases of confinement were attended. The work of the two semi-convalescent homes is shown by the number of patients drafted from the infirmary to the Ida and Robert Arthington Hospitals, for this is the only way these institutions are filled. The number for 1908 was 1,154. These hospitals had a daily average of 84 patients, and the average number of days spent by each patient in them was 24.9. The total amount of alcohol—including in this both wine and spirits—consumed in the infirmary during the year 1908 was 6,428 oz. (2,021 being wine and 4,405 spirits). This means about 18 oz. daily, and, when one considers that the average number of patients was 365, the amount used is surprisingly small. Last year, with 368 patients, the amount used daily was 27 oz. In 1905, with about the same number of patients, the amount was rather more than double that used during 1908, but, as was pointed out, this larger figure represented only one-tenth of an ounce per patient per day.

BRISTOL.

TERRITORIAL FIELD AMBULANCE.

UNDER the Territorial Force scheme, the medical part that was allotted to Bristol was the raising of a field ambulance to be attached to the Gloucester and Worcester Battalion of the South Midland Division. After a few preliminary meetings, at one of which Colonel Russell, R.A.M.C., explained the general scheme, recruiting was started, and

on May 17th, 1908, a sufficient number having been enrolled, the corps received official recognition, under the command of Lieutenant-Colonel A. W. Prichard, V.D. At the time of the annual training, 98 men and 7 officers went into camp for a week at Swanage, followed by a second on Salisbury Plain, a no mean muster for a corps only formed a few months. Since that time to the present recruiting has been most satisfactory, resulting in the corps not only being up to its establishment, but, owing to its having a certain number of special reservemen in the ranks, being at least 10 above. Both before and since camp lectures founded on the *Manual* have been given by the officers, and parades for recruits and company drill have taken place twice or three times a week. Unfortunately the corps is as yet without its own head quarters, and is at present obliged to share the drill hall of the 4th (City of Bristol) Gloucester Regiment, and though there is little prospect of a drill hall of their own being provided by the County Association, it is still hoped that some more commodious place will be found soon. As it is almost impossible to parade the whole corps at once, but as the summer comes on the cricket ground of the Bristol Grammar School will be kindly lent by the head-master, Captain Norwood. The corps is no better off than the London ones seem to be as regards wagons, etc., and all the stretcher drill so far (with the exception of work in camp) has been done with stretchers lent by the Marine Ambulance, a civilian corps in Bristol. Instruction in the care of horses, in harnessing, etc., is now being undertaken, and the officers will begin again their weekly rides, which were only stopped by the dark days and pressure of professional work in the winter. As a special mark of approval the corps was in August last permitted by the War Office to wear gold ornaments. The school of instruction for officers is now being held by the Adjutant, Captain Stephens, R.A.M.C. It is believed that the 3rd South Midland Field Ambulance is the first in the United Kingdom, other than a cavalry ambulance, to attain its full establishment of men. It is true that two more officers are required, but this deficiency will probably be soon made good.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

INDIAN MEDICAL SERVICE DINNER.

We are requested to intimate that the annual dinner of the Indian Medical Service in Edinburgh will take place, as formerly, in the Caledonian United Service Club, Shandwick Place, on the last Friday in May next, under the Presidency of Sir Alexander Christison, Bart.

This early intimation is given so that it may reach those officers who contemplate taking furlough previous to their departure from India. Those wishing to be present should write to Brigade-Surgeon James Arnott, 8, Rothersey Place, Edinburgh.

ROYAL EDINBURGH ASYLUM FOR THE INSANE.

The annual meeting of the Corporation of the Royal Edinburgh Asylum for the Insane was held in the City Chambers, Edinburgh, on Monday, February 22nd, the Lord Provost presiding.

Dr. G. M. Robertson, the physician superintendent, submitted his first annual report for the year 1908.

At the beginning of the year the total number of patients in Craig House and the West House, the two establishments which form the Royal Edinburgh Asylum, was 743 (including 10 on probation), and on December 31st it was 752 (including 11 on probation). The admissions were 239 (106 men and 133 women). The total number of patients under treatment was, therefore, 982. The number discharged was 166 (89 men and 77 women). The number of patients who died was 64 (29 men and 35 women). The average number of patients resident during the year was 733 (356 men and 377 women).

The admissions were 78 less than in 1907. During the last three years the admission-rate had been steadily falling, owing to the fact that the Parish Council of Edinburgh had every year been sending a larger number of its mental cases to Bangour Village Asylum and fewer to the West House. Edinburgh patients still continued to be admitted to the West House, as the managers were under an obligation to find accommodation for 105 patients belonging to that parish till the year 1914.

The number of private patients admitted was 132, or 3 less than last year, which was the highest in the history of the institution. These admissions were chiefly to the intermediate department of the West House, where accommodation and treatment were provided at the standard rate of £45 a year. This department was one in which the managers had always taken the greatest interest. They had dealt with the patients undergoing treatment in it in the most generous manner, and it was calculated on that account that there was a loss sustained in its management last year of £3 a head. This special interest was due to the fact that this department provided accommodation of a comfortable character for the afflicted members of families of the educated and professional classes of only moderate means. These families were quite unable to afford to pay the considerably higher rates charged at Craig House, and patients of this class would suffer in many ways if placed for treatment among rate-paid patients of a different social position. Separate accommodation to meet this want was only found in the Royal Asylums of Scotland, but up to the present time the extent of this accommodation had not been sufficient to meet the demands. Owing to the removal of the patients belonging to the parish of Edinburgh, adequate space was now available for this purpose at the West House, and this was proving a benefit to a most deserving class who were promptly taking advantage of the available accommodation. In providing this accommodation the managers felt that they were locally carrying out what was one of the primary objects of the founders of the institution—"to extend the benefits of the institution to such persons as are in circumstances of indigence," but who are above pauperism. The managers were anxious that the existence of this accommodation should be as widely known as possible throughout Scotland to those whom it concerned.

With regard to the character of the cases admitted, Dr. Robertson made the following observations:

There were sixteen men and ten women admitted who were diagnosed by the medical officers to be suffering from alcoholic insanity, being 10.8 per cent. of the total admissions, a proportion which compared favourably with previous years. A more remarkable feature was the fact that eleven persons were admitted suffering from post-influenza insanity, being nearly 5 per cent. of the total admissions, and 42 per cent. of the admissions directly due to alcohol. The poison produced by the influenza microbe was recognized by mental physicians to have most injurious effects on the functions and tissues of the brain and nervous system. As a rule these effects were not immediate, as the poison acted slowly by impairing the health and nutrition of the nerve cells, and after the patient had been out of sorts for a fortnight, a month, or even much longer, the mechanism of some nervous function or other broke down. These nervous after-effects were legion, and fortunately in only a few cases did they result in complete mental derangement. The extent of the mental, physical, and material damage, indirect as well as direct, sustained by the nation as the result of influenza could only be realized by comparing it with that produced by excessive indulgence in alcohol. For one patient sent to the asylum there were scores who were incapacitated, and the ill-health of these was a source of misery to themselves and, if they were breadwinners, of consequences for their families as serious as would have been the case had the head of the household been a drunkard. It would have been better for the country had an epidemic of cholera passed as a scourge through the land and then left it, than that it should be afflicted as it was by recurring outbreaks of influenza.

The percentage of recoveries was 31.3 of the total admissions—considerably below the average. Since 1900 the total number of deaths was 64, which was less than for twenty years. The percentage on the average number resident was 8.7. The treatment of consumption was being carefully carried out on modern lines. It was a disease that could be kept thoroughly under control in an asylum. General paralysis caused 18 deaths—14 men and 4 women.

Reference was made to the general history of the institution, the retirement of Dr. Clouston, that enduring monument of his régime, the Craig House. The inception of the idea to build a great mental hospital designed on modern lines for the accommodation of patients able to afford high rates of board, and desirous of getting the very best care and treatment that could be obtained, showed great boldness as well as remarkable foresight. The manner in which this idea was carried out was even more remarkable. The resignation of Mr. Gregory, head attendant on the men's side, had allowed the new arrangement of a lady superintendent undertaking the responsibility for the supervision of the nursing and domestic arrangements of the institution.

Miss Wise, lately matron on the ladies' side, had been appointed to this. A nurse's home was to be arranged at the West House. The work being done at the laboratory of the asylum was referred to. Dr. Winifred Muirhead had been appointed Pathologist. The lactic acid bacillus treatment had been employed in treating those chronic cases the result of a faulty chemistry in the disease, and more frequently produced by micro-organisms which have invaded the body. In association with Dr. Dods Brown, Dr. Ford Robertson, the pathologist of the Scottish asylums, had obtained further support for his hypothesis of the causation of general paralysis.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

ROYAL COLLEGE OF SURGEONS.

THE annual dinner of the Royal College of Surgeons in Ireland was held on Saturday, February 20th, when the chair was occupied by Mr. J. Lentaigie, the President. His Excellency the Lord Lieutenant honoured the proceedings by his presence, and there was a distinguished general company. The occasion was made specially interesting by the presentation to Professor Alec Frazer of a silver box containing a handsome cheque from the college staff, in commemoration of the completion of twenty-five years' work as teacher of anatomy. The President said he was the trusted friend and counsellor of the students, and had a wonderful gift of imparting knowledge and of controlling and directing his pupils. Professor Frazer was enthusiastically cheered in acknowledging the honour. Many toasts were proposed, and among the speakers were the President, His Excellency Lord Aberdeen, Mr. R. H. Woods (Vice-President), Mr. Justice Kenny, the Provost of Trinity College, Rev. T. A. Finlay, S.J., Sir Arthur Chance, and the President of the Royal College of Physicians.

Canada.

TORONTO MILK COMMISSION.

A COMMISSION has been appointed by the Academy of Medicine, Toronto, to obtain, if possible, a supply of milk of a high standard of purity, to be known as certified milk; the requirements for this standard are as follows:

1. The herd milk shall contain 12 to 13 per cent. of total solids, of which 34 to 43 shall be of butter fat.
2. It shall contain no colouring matter, preservatives, or other foreign substances.
3. It shall be free from blood, pus, or disease-producing organisms.
4. It shall be free from all disagreeable odours and tastes.
5. It shall not have been heated in any way, nor frozen.
6. It shall be derived only from cows which have been tuberculin tested by the veterinarian of the Commission before entering the herd, and have been found healthy, and which shall have been so tested every six months thereafter.
7. It shall have been cooled to 45° F. within one half-hour after milking, and shall be kept at not higher than 45° F. until delivered.
8. It shall not be more than twenty-four hours old when delivered to the consumer.
9. It shall not contain during the months of June, July, August, and September more than 10,000 bacteria per cubic centimetre, as shown by a forty-eight hour culture on nutrient agar medium at 37° C., nor in the remaining months of the year more than 5,000 bacteria per cubic centimetre as demonstrated by the same tests.
10. The veterinary inspector and the physician of the Commission shall each month inspect the herd, the health of the employees, and the hygienic conditions of the dairy generally.
11. All bearers of a physician's prescription for certified milk shall be deemed preferred customers.

A circular of recommendations has been issued to the dairymen of the city and vicinity, pointing out the method to be followed to meet these requirements. The stables and barnyard are to be kept clean, light, and well ventilated, with a constant supply of good water; the cows are to be groomed, and the inside of the thighs and the udders washed before milking; all milk from cows twenty-one days before and seven days after calving is to be rejected. The milkers are to be personally clean, and in case of illness in the person or family of any employee, he

must absent himself until he procures a doctor's certificate that it is safe for him to return. The hands are to be well washed and dried before milking, and light-coloured, washable garments are to be worn; children under 12 years of age are to be excluded from the stables, owing to their liability to contagious diseases; also cats and dogs, which may frighten the cows. The first few streams are to be discarded from each teat, and the milk pails shall have a diameter not exceeding 8 in. at the opening. All dairy utensils, including bottles, are to be cleaned and sterilized by washing in hot water and soda with a brush, and then sterilized with flowing steam for one hour or with steam under one atmosphere for fifteen minutes. The sterilizing room is to be separate from the bottling and cooling room. The bottles, after filling, are to be capped with a sterilized paper disc, bearing the seal of the Commission and the date of production.

In order that the dealers and the Commission shall be kept informed of the character of the milk, specimens will be taken at random from the day's supply once a month or oftener, and subjected to examination by the experts of the Commission. The Commission will make inspection of certified farms at frequent intervals, and reserves the right to change its standards in any reasonable manner upon due notice being given to the producers.

The Commission is ready to certify to the milk of any producer who fulfils the above standard to its satisfaction, and already two large dealers have accepted the responsibility. The Academy of Medicine in appointing the Milk Commission, is actuated by a desire to obtain for the children and patients under their care a milk beyond suspicion; the motives of the Commission are disinterested, and its members forbid to themselves any pecuniary reward.

Special Correspondence.

VIENNA.

Scarcity of Water.—Conditions in the Army Medical Corps.—A Hospital Strike.—Teaching of Social Medicine and Medical Ethics.

The abnormal conditions of weather and climate which have prevailed in this country since September, 1908, have had a very unpleasant effect on the water supply of the capital. In normal times Vienna requires about one and a quarter millions of hectolitres of water, or about thirty millions of gallons, per day. This quantity of water is supplied by a number of mountain springs coming from the group of the Schneeberg, about 6,000 ft. high. An aqueduct, some 78 miles long, brings the water to Vienna. To this abundant supply of fresh, cool, and healthy water the absence of typhoid in Vienna is ascribed. In the months of September to December the rainfall for this particular district was not even a third of that coming down there as a rule, and when frosts set in at Christmas time the water supply was still more interfered with. The store of water in the reservoirs in Vienna had to be drawn upon; the water pipes in the houses had to be throttled; the use of water was diminished as much as possible, so that the daily requirements were brought down to about 50 per cent. of the normal. But now even this amount does not flow into Vienna, so that the city is suffering from a water famine. The water necessary in hospitals and other similar institutions was not cut off, but in many houses and in industrial buildings this had to be done. Luckily the weather has within the last forty-eight hours turned very warm, so that the reservoirs and the houses will soon get their full share of water again.

The recent warlike rumours turned public attention to the fitness of the army, and the complaints against the administration of the Army Medical Corps have been publicly discussed in a very animated way. The object lessons taught by the war in Eastern Asia have shown sufficiently that fitness for war includes also fitness of the medical provisions. But in the army racial and religious prejudices have been allowed to interfere with promotion, so that within the last seven years 747 surgeons have decided to throw up their commissions. On the other hand, the pay of the medical corps has remained stationary for twenty years notwithstanding the increase in the cost

of living. Private practice and appointments offer greater attractions to the young doctor than the military career does at present. The result is that there is a lack of medical officers in the army, believed to amount to 500 or more. Every effort is now being made to remedy the disgraceful and dangerous state of affairs.

A "hospital strike" lately gave rise to much comment in medical circles of the city. In one of the smaller public hospitals the medical staff had complained several times to the managing board about the administrative work and the non-medical duties they were expected to perform. Lately the quality of the food had also become, on account of the cheeseparing policy carried out by order, rather of a low kind, so that the whole medical staff refused to continue their work and "struck." This had the desired effect. The public scandal and the indignation at such a method of economy quickly put things right, and the food will in future be controlled in the kitchen by a doctor. The strike has shown once more the good effect of co-operation amongst medical men.

In one of the latest meetings of the Vienna Medical Council (Aerztekonferenz) Dr. Grün proposed that a petition should be presented to the Government asking for the establishment of special chairs of social medicine at the Vienna University. He suggested that the student should be instructed (1) in the relations between the doctor and the general public, the authorities, and the legislature; (2) the importance of medical organization and the duties of the practitioner towards it. The main subjects should be: Physician and patient; the rights and duties of the physician in regard to his patient and the public; the duties of the physician in regard to his brethren in private practice (instruction in medical ethics); rights and duties of the doctor in relation to contract practice and sick clubs, insurance companies, and accidents; the relations between old-age and invalid pensions and private practice. Special care should be devoted to medical testimonials and examinations; the duties of the practitioner towards the State in infectious diseases and occupation or industrial diseases. The important subject of social hygiene should also form part of this study. The latter would comprise the history of social hygiene, social statistics, and special hygiene (of schools, of building, of food, of epidemics). The suggestion was received with great applause, and will be made the subject of general discussion.

Correspondence.

THE BIO-CHEMISTRY OF CYTOLYSIS.

SIR,—In the interesting account published in last week's *JOURNAL* of the Morison Lectures, by F. W. Mott, M.D., F.R.S., F.R.C.P., on the Pathology of Syphilis of the Nervous System in the Light of Modern Research, a passage occurs in which Dr. Mott rightly draws attention to the great importance of the cell lipoids, not only in the normal life of the cell, but in the bio-chemistry of such reactions as the Wassermann test for syphilis and in the neutralization of cobra venom by lecithin, which is here the active constituent of the lipid.

While subscribing in full to this opinion, I should like to be allowed to point out that there is an alternative view to that which supposes that the lipoids owe their activity to the formation of an osmotic membrane, consisting of a mixture of lecithin and cholesterolin around the cell, which conserves the cell contents and preserves a different composition from the surrounding plasma.

It has been shown in detail by Moore and Roaf (*Bio-Chemical Journal*, vol. iii, p. 55, 1907) that any such inert membrane cannot give rise to the distribution of salts and colloids within and without the cell, which naturally occurs; that it can only prevent passage of dissolved substances to and fro, but cannot explain accumulation of cell products in higher concentration within the cell than in the plasma.

The alternative view, for which evidence is given in the paper quoted, is that cell proteins and cell lipoids are unsaturated bodies capable of entering into a labile equilibrium with the other cell constituents and with each other. The amount of such loose physico-chemical combination varies up and down with the cellular activity

and changes in the environment from moment to moment, and there is thus a flux of chemical energy going on all the time in a system which is stable though all the time undergoing change.

This view is far more compatible with the reactions shown to occur with the isolated lipoids and cobra venom, or of the lipoids, such as lecithins and oleates, and the antigen of syphilis, than any membrane hypothesis, for here there is no doubt whatever of the existence of chemical reaction.

The writer has shown by experiment that lipid matter as a membrane does not possess the osmotic properties theoretically assigned to it by Overton, and it is far more probable that the lecithin and other fatty bodies are distributed all through the cell substance, in combination with the haemoglobin forming a cement substance for it, than that they merely form a superficial stroma or membrane for the corpuscle. There is no doubt whatever that the stroma left behind when the haemoglobin escapes is not lipoidal in character, this other stroma of lipid character acting as an osmotic membrane is a theoretical myth which has never been demonstrated by staining or otherwise.

The part played by lipoids both in health and in disease is one of large importance, which is just now being gradually realized, but it is as active chemical constituents of the cell of an unsaturated nature and therefore capable of combining chemically with proteins, toxins, anaesthetics, drugs such as digitalin and saponin, and many other physiologically potent substances, and not merely as inert membranes, that this class of bodies exercise their influence.

This is shown by their similar chemical activity when entirely dissolved out of the tissues so that they cannot in any sense be acting as membranes, yet they still neutralize cobra venom or syphilitic antigen.

The nature of the reaction between these lipoids, the immune body, and the complement of serum is a biochemical problem of the profoundest interest.

Work which I have recently carried out on the nature of the reaction induced by the oxidizing ferments or peroxidases led me to the view that the lipoids might be reduced substances, and the complement an oxidizing body, and experiments conducted on this basis by Dr. F. P. Wilson and myself bearing on the haemolysis of blood corpuscles by reducing and oxidizing agents have yielded most interesting results, of which the following is a brief preliminary account:

All naturally occurring lecithides are unsaturated and capable of taking up oxygen, for all contain the unsaturated oleic acid. Also it has been shown by Sachs and Altmann that sodium-oleate binds complement in presence of syphilitic serum similarly to the antigen of syphilis; further, such oleins are set free in nervous lesions, and would be present in syphilis and in general paralysis.

Acting on this hypothesis we have tested the action of hydrogen peroxide as an oxidizing agent and ammonium sulphide as a reducing agent upon washed blood corpuscles, both reagents being used only in extreme dilution, and we have found that the oxidizing agent produces haemolysis, while the reducing agent inhibits and entirely prevents haemolysis even in presence of extremely active haemolytic serum.—I am, etc.,

BENJAMIN MOORE,

Bio-Chemical Department, University of Liverpool.

February 22nd.

THE SERUM DIAGNOSIS OF SYPHILIS.

SIR,—In connexion with Dr. Mott's remarks in his recently-delivered Morison Lectures on the Wassermann test, may I be permitted to point out that Dr. Porges, one of Professor v. Noorden's assistants, has, conjointly with others, devised a method of the serum diagnosis of syphilis which he claims to be an improvement on that of Wassermann? The test, as I saw it performed, was as follows:

1 to 2 c.cm. of blood are taken from the finger and transferred to a small test tube. The corpuscles are allowed to sink, and the upper serous portion is drawn off. This is then centrifugalized, and the serum again drawn off and heated in a water bath for half an hour to a temperature of 56° C. By means of a finely-graduated pipette, 2/10 c.cm. of the heated serum is transferred to a test tube A, and a similar quantity to a second test tube B (control). To test tube A is added 2/10 c.cm. of a

freshly-prepared solution of sodium glycocholate (1 per cent. of the salt in distilled water), the two fluids being mixed by carefully inverting the tubes a few times, and to test tube B is added a similar quantity of normal saline solution. The two tubes are kept at the ordinary temperature of the laboratory for about twenty hours. In the event of a positive reaction, at the end of this time a flocculent precipitate will be observed in test tube A floating in the upper portion of the fluid, the fluid in test tube B remaining, on the other hand, quite clear.

It is not maintained that the absence of a reaction (= negative reaction) is proof positive that the patient experimented on has never had syphilis; it is, however, contended that a positive reaction is definite evidence of past syphilitic inoculation: 60-70 per cent. of tabetics give a positive reaction and 80-90 per cent. of general paralytics. Dr. Porges kindly demonstrated this test to me, and I had the opportunity of seeing the characteristic flocculent precipitate in one of the laboratories of the Allgemeines Krankenhaus twenty hours after the initial processes had been completed. The occurrence of this precipitate was eloquent indeed, for here we had evidence, visible to the naked eye, that the blood of a syphilized individual many years after the primary inoculation differed from normal blood in a very definite way. Dr. Porges maintains that this test is not only simpler and more easy of application than the Wassermann test, but that it gives better results. I found, however, that the two medical residents in charge of the syphilis block at the Städtische Klinik at Frankfurt placed greater reliance on the Wassermann method.—I am, etc.,

London, W.

HARRY CAMPBELL.

PULMONARY TUBERCULOSIS IN CHILDREN.

SIR,—I have the good fortune to live in the district covered by Dr. Williams as Assistant Medical Inspector of School Children. Three of these so-called phthisical cases excluded by Dr. Williams from school have appeared with their mothers at my "out-patients" at the Kidderminster Hospital, bearing a letter stating that the child has tuberculosis of the lungs and needs medical attention, the mothers not unnaturally being in a great state of perturbation. In not one of these cases could I find any physical signs of tuberculosis of the lungs whatsoever, and I do not think that I belong to that class of medical men which from Dr. Williams's paper one infers exists, and which Dr. Walter Carr has boldly crystallized into words. These are the only three cases, so far, that I have seen that have been excluded by Dr. Williams for this so-called "consumption of the lungs."—I am, etc.,

BERTRAM ADDENBROOKE.

Kidderminster, Feb. 23rd.

SIR,—Dr. Mary Hamilton Williams, in her interesting paper on Pulmonary Tuberculosis in Children, in the BRITISH MEDICAL JOURNAL of February 13th, says: "The number of children on the rolls in the London schools examined was 165,915. Therefore, the probable number suffering from phthisis among these was . . . 7,164—that is, it is probable there were roughly 7,164 children suffering from phthisis in the schools examined."

But why "in the schools examined"? Why not in bed or at the hospitals? Not every child on the roll is "in the school." I have not got the London figures before me, but, in my own county area of Staffordshire, the children "in the schools" are commonly only 90 per cent. or 93 per cent. of those "on the roll." Thus, last month we had 81,341 on the roll but only 73,757 in the schools—a difference of 7,584. If Dr. Williams's statistical inferences are correct, and if, further, we in Staffordshire have the same proportional number of phthisical children as her figures seem to show for London—namely, at out 3,500—we should have an ample margin of absentees to account for them.—I am, etc.,

Stafford, Feb. 20th.

JOHN PRIESTLEY.

SIR,—In reading the paper on Pulmonary Tuberculosis in Children, by Dr. Mary Hamilton Williams, in the BRITISH MEDICAL JOURNAL of February 13th, I was so surprised to find that she considers phthisis is one of the most common diseases of children, that I immediately looked up my notes on the subject. I am quite convinced that it is one of the rarest diseases of childhood. Among my out-patients at the General Hospital, and at the Children's Hospital, Birmingham, I have taken the last

8,000 cases of children under 15 years of age, whom I have examined, and find that I have diagnosed phthisis in only 15 patients. Of these, 4 have already become quite well again, and another has greatly improved, so that I consider my diagnosis was wrong in all five; this reduces the number to 10, or 0.125 per cent. There were 11 others which I thought were doubtful cases of phthisis on my first examination. One appeared later to be a case of bronchiectasis, and all the others which I have not lost sight of completely recovered. There were other cases of tuberculosis of the lungs, but in them it was associated with tuberculous lesions elsewhere in the body, or the condition followed pneumonia which was tuberculous from the beginning.

There were about 12 cases of general tuberculosis, but I do not know the exact number, as they were admitted directly as in-patients; there were 2 cases of tuberculous peritonitis, which had undoubtedly tuberculous foci in the lungs; and 3 cases of bronchopneumonia which I considered to be tuberculous. Of course, a large proportion of these children whom I examined were below the school age, but, if so small a number appear to have tuberculosis of the lungs in children who are ill and are brought to a hospital, surely a much smaller number suffering from this disease should be found in school children of whom the great majority are in good health?

Naturally, errors in diagnosis may be made, and so I turn to my *post-mortem* notes for confirmation. While Pathologist at the General Hospital, Birmingham, I performed myself 244 *post-mortem* examinations on children under 15 years of age, and have attended many *post-mortem* examinations since. Of the 244 cases, there were 13 of general tuberculosis in which the lungs and bronchial glands were affected. In most of these the condition of the lungs was one of acute miliary tuberculosis, but in 4 there were many small cavities and caseating foci. There were 3 cases of tuberculous meningitis, in which there were caseating foci in the lungs and bronchial glands. In 1 case of cerebral tumour of tuberculous origin there was one caseating mass in the apex of the right lung, and the kidneys and the mesenteric glands were tuberculous. There were 2 cases of tuberculous bronchopneumonia, in both of which the bronchial glands were affected, and in one the mesenteric glands. There were, therefore, 19 cases of tuberculosis of the lungs, but in all except 2 the disease was disseminated widely in the body. I should add, however, that phthisis is not usually admitted into the General Hospital, but when we consider how frequently we find evidence of recent or past phthisis in the *post-mortem* examinations of adults, and that it was only in 2 cases out of 244 of children under 15 years of age that tuberculous lesions were found in the lungs only, and not disseminated over the body, we must conclude that phthisis is a most rare disease in childhood. The 2 patients with tuberculous bronchopneumonia were acute cases, and did not present the condition which is usually spoken of as phthisis.

Dr. Mary Hamilton Williams calculates that there were 165,915 children on the rolls of the London schools examined, and that among these the probable number suffering from phthisis was 7,164. This means that 4.318 per cent, or 1 in 23, of school children suffered from phthisis in these schools, whereas my figure is 0.125 per cent., or 1 in 800, for all children up to 15 years of age who attended the out-patient department of a general and a children's hospital. I therefore record my figures because they seem so contrary to the opinion of Dr. Mary Hamilton Williams, and because they appear to me to prove that phthisis as observed in the adult is one of the rarest diseases of childhood.—I am, etc.,

Birmingham, Feb. 20th.

JAMES E. H. SAWYER.

THE APPLICATION OF MENDELIAN RULES TO HUMAN INHERITANCE.

SIR,—“If,” says Dr. Drinkwater, “there had been no children born to the last abnormal . . . without doubt Mendelians would have considered Nettleship's chart as conforming to Mendel's rules.”

I do not feel in a position to say what Mendelians would have considered. Personally I should have said that this astounding association of the last abnormal with sterility was not in accord with any known law of Mendel,

and, until an explanation of it was forthcoming, that it was idle to talk of any proportion as near enough to that required by theory. It would have upset Mendelian theory by the simple fact that it postulated a special genetic constitution for the last abnormal.

Dr. Drinkwater asks me to furnish my explanation of what he terms the striking fact that of 98 abnormal parents nearly one-third had normal children only. My reply is that such a fact is only “striking” when you have demonstrated that it does not occur in other forms of pathological inheritance. It is necessary to remind Dr. Drinkwater that it was he, not I, who asserted that night-blindness closely obeyed Mendelian rules; that it was he, not I, who without any public acknowledgement of the fact calculated proportions by a non-Mendelian rule of his own; that it is he who is, not I who am, called upon to explain what he has but I have not yet termed a “striking fact.”

Dr. Drinkwater now agrees apparently with the view I thought he held from the beginning, namely, that prepotency may change not only with the mating, but even in the mating. There may, in my opinion, be much or little to be said for that view; all I would suggest is, that it is wholly incompatible with the theory of the pure gamete, and with the orthodox Mendelian's principles of dominance and quantitatively definite segregation which are hardly likely to be discarded by professed Mendelians. Above all from the standpoint of medicine, it would render Mendelism useless as a method of prediction.

Dr. Drinkwater tells us now with regard to this night-blind pedigree that there is no escape from the conclusion that some new factor must have come into operation where Mendel's rule begins to be inapplicable. I do not quarrel with this statement, but I ask why was it not distinctly stated in the original lecture (as printed in this JOURNAL), where the night-blind pedigree was described as giving the orthodox Mendelian ratio?

We are not at the bottom of the inheritance of night-blindness. There will, I feel quite certain, be other difficulties to be cleared up about change of dominance, when we have before us ten or a dozen pedigrees. Meanwhile I would return to my original standpoint—the urgent need to put aside controversy as to theory and patiently collect and publish raw material. In spade work of this kind Dr. Drinkwater has done excellent service, and as far as the inheritance of pathological characters in man is concerned this is the work which must precede all profitable analysis.—I am, etc.,

University College, London, Feb. 19th.

KARL PEARSON.

SIR,—Under this title a discussion has been recently proceeding between Professor Pearson and Dr. Drinkwater. I have followed it with some interest. Professor Pearson may not intend to mask the fundamental issues which arise from the discussion, but, none the less, that is what he has accomplished. Some day the mathematician will succeed in learning that living structures are not dead marbles, and that mathematical conceptions and formulae which may be legitimately applied to the latter have not always a valid application to the former. I will, therefore, meet Professor Pearson on his own battle-ground, and there I extend to him an invitation. He says: “In fact, the odds are several millions to one against Nettleship's material being a sample of a population obeying Mendel's rule.” No doubt it is easy to make such a statement and to create an imposing impression; and it is, doubtless, just as easy to believe that a faith in the infallibility of authority will cause it to be accepted without further question. But I am sorry to say that I am not one of the faithful. Indeed, I am very sceptical, and therefore I call for proof. I am acquainted with some of Professor Pearson's mathematical methods and conclusions, and I have learned that sometimes among the mathematical formulae there is hidden away a great deal of very un-mathematical assumption. Now, the outcome of any problem in probability depends upon the accuracy of our knowledge of the conditions and factors upon which the probable event depends. It will be of very great interest, therefore, if Professor Pearson will vouchsafe to let us into the inner sanctuary of those intellectual processes by which he arrives at a knowledge of these conditions. In

other words, we would all like to see and follow the various steps in this problem in probability by which this sweeping conclusion has been reached. It will require, I think, another mutational Laplace to evolve the needful processes of demonstration.—I am, etc.,

THE COLD-BATH TREATMENT OF TYPHOID.

SIR,—In the JOURNAL of January 16th, p. 185, there is a letter from "X." which I have read with great interest, and wish to record my experiences with cold sponging of typhoid cases for the last ten years on Mount Lebanon.

I have never tried the cold-bath treatment on Mount Lebanon because I found the system so troublesome and impracticable in any ordinary private house. Although I cannot give your correspondent satisfactory statistics of all the typhoid cases I have met with, I am convinced to say that cold sponging does replace the cold-bath treatment of typhoid, and is efficacious in every way. Last month I had under my care fifteen cases of enteric fever; all were treated with cold sponging twice a day, and all recovered.

It may interest your correspondent to notice that my usual internal treatment for typhoid cases is tincture of iodine and salol or beta-naphthol.—I am, etc.,

Beirut, Syria, Jan. 21st.

A. J. MANASSEH.

THE DRAFT CHARTER.

SIR,—The letter from the Cape of Good Hope in Saturday's JOURNAL calls for strong protest from those who have been pressing for amendment of the draft Charter before it is accepted by the Privy Council. The writers have no right to charge us with a desire to wreck the Charter. We are as wishful as they are for the powers which they demand, and only claim that the rights of the individual member should be safeguarded, and in other less laudable objects that the voice of the Association should be tested by an efficient Referendum. With regard to the first claim, they forget that the postal vote is to be granted to the Colonial members and denied to us. Then, with regard to the second, let us recall the vote they gave almost unanimously against the proposals of the Representative Meeting in the Referendum of 1907. The Eastern Provinces at the Cape were solid against these proposals, and the Western Provinces did not vote at all. Only two of the ten Divisions in the whole of the Colonies supported the Representative Meeting. No fewer than twenty-two Divisions held no meeting, or recorded no vote. In these circumstances it is hardly reasonable that they should seek to hurry on legislation which they so recently condemned. It is also highly improper that they should fasten the charge of obstruction on those who are claiming privileges which they are to enjoy.

As usual, the threat of secession from the Association is again brought forward, as it was in July, 1906, and in May and July, 1907, as a reason for dispatch. We have never condescended to that line of argument, though the risk is far greater in our case. We have even been invited to fall away as "leaves," and almost threatened with expulsion.

Is compromise not possible? Dr. Taylor's letter of January 23rd, p. 247, deserves serious consideration. If the Charter is granted in its present form, there will be discontent in the Association, if not disruption. Without committing anyone else, I think his suggestion contains the germs of an amicable arrangement. There are subjects which demand discussion in Division meetings, and others which need none. If these questions were classified by mutual agreement, and the latter submitted to a postal vote, if a statutory quorum were fixed for all meetings at which delegates were elected or instructed, and if the Council were granted more unfettered power in taking the Referendum, the unanimity of the Association might be secured in favour of the Charter.

It may be that the members of the Association are prepared to accept the Charter as it is, but the vote of less than 10 per cent. is not decisive, and it is all the Representative Body has at its back, less the Divisions which voted against it in the 1907 Referendum. We believe, on

the contrary, that if the members were polled individually a large majority would support our demand. We desire to test the true feeling of the electorate, and it shows little confidence in the strength of their case that the demand was rejected by the Representative Body.

Even if it involve a little delay in the granting of the Charter it would be a momentous gain to the Association if we could arrive at an amicable compromise. We recognize the enormous amount of labour and skill in the drafting of the Charter, and in no way impugn the sincerity of its authors, and it would be far more in accordance with our wish to bless than to ban it, but we will not agree to the extinction of the right of franchise to the member who honestly is unable to attend the meeting of his Division, or the right of the Council to refer, with a fair prospect of success, any matter which it believes is not in accordance with the true interests of the Association.—I am, etc.,

Edinburgh, Feb. 22nd.

A. WALKER.

THE REPORT OF THE PUBLIC HEALTH COMMITTEE.

SIR,—The medical officers of health of small districts have been on public view now sufficiently long to judge of their efficiency and usefulness. By their works shall we know them. Statistical results tell their own tale. The health record of small areas compares most favourably with that of large areas. What advantage, then, would ensue from a public health point of view in doing away with the intimate local knowledge of the local medical officer of health? He is always on the spot, ready to deal promptly with infectious cases. A whole-time man cannot be in two or three places at once. Moreover, ratepayers are beginning to kick against the tendency of over-centralization, as they know that their local needs are best understood by the man whose daily round takes him all over the district, and whose interest is identical with the health and prosperity of the place wherein he earns his livelihood.

The bogey of the medical officer of health bagging other local practitioners' patients has long been laid to rest. This and the other delusion—that the medical officer of health is afraid to do his duty for fear of being unpopular—are mutually destructive. There may be general practitioners so morbidly jealous that they view with jaundiced eyes even the obituary notice of a fellow practitioner. But we need not legislate for envious freaks.

The British Medical Association will be doing a useful work if it helps to obtain greater security of tenure of office and automatic increase of salary, as obtains in all other public services and in most private employment. Let its work be constructive, conservative, consolidating, and strengthening, not destructive and disheartening to the local medical officer of health.—I am, etc.,

AUGUSTUS H. BAMPTON,

M.O.H. Ilkley.

February 16th.

THE CONFERENCE ON FRIENDLY SOCIETIES AND THE MEDICAL PROFESSION.

SIR,—Having always been intensely interested in the question of "contract" practice for medical men, I make that my excuse for putting pen to paper, as the recent conference appears to show that some members, at any rate, of our profession have the courage of their convictions.

The one fact that stands out as a source of never-ending astonishment to me is, that *any* medical man worth his salt should do *any* work on a contract basis. For what is a medical man? He is, I take it, a man who says in effect—You, or yours, sir, are unfortunately ill and suffering. Very well, I will use my utmost endeavours to get you well in the shortest possible time, bringing to bear upon your case thought and whatever knowledge I possess (nor did I acquire habits of thought, or knowledge, without very hard work and much money spent), and your good health—strange as it may seem—is my earnest desire. For this I expect, as every other man does who uses his brains, a reasonable fee in order to live.

But when a man (or body of men) comes to a doctor and says, "I will give you so much a year to attend me (or me and my family, or us), whether we are sick or not," in my opinion the doctor who accepts such an

offer forgets what he has been educated for, forgets that he and his friend are "human," forgets what the nature of a bargain is. The whole thing is so absurd that it really seems hardly worth while to labour the point. I am told, or have been told often, that the English working man stands as the exponent of "fair play." A fair day's work and a fair day's pay! I suggest, Sir, that he often fails to grasp the first principles of fair play. Now, what is the remedy for all this?

I see in your issue of February 13th a letter from "One Who Tries to Play the Game." (What does this signature mean, I wonder?) He is right. "Much talk and little treatment" is at present the trouble (and always has been). Then he hits the nail on the head when he says: "The education of the public may be achieved in time if we reform within the profession." Exactly! I have been wondering of late what precisely "a humble member of the rank and file" gains by belonging to the great British Medical Association? The discussion on the proposed "Royal Charter" has been somewhat entertaining, even if one has been inclined to whistle and stick one's tongue in one's cheek! There is certainly food for thought. In my own humble sphere I have always said to myself that I would rather starve or take up another profession than endeavour to increase a paltry enough income by accepting "contract" work. Are the body of the profession afraid, I wonder? I wonder also that they never even look at it in this light: That it is preferable to obtain a little more leisure—time to read, to think, to enjoy life, and last, but not least (most mundane and gross thought!), to eat—rather than accept a club or clubs to increase their income for work which they cannot possibly do well at such a price.

Finally, Sir, it may perhaps be worth while recording that I know of a branch club where recently it was proposed to pay the doctor on the principle of so much per visit and medicine. They agreed to try it on the doctor's terms. The first year of the experiment the club happened to benefit by the arrangement—but the doctor had less work.

One could say so many things on this subject; but I think I have said enough to show that it is we doctors who ought to "play the game," and gain a little respect in the eyes of the world by firm action. As Mr. Smith Whitaker rightly said at the conference, we want no favours; we want no money for work not done; nor is "money" everything.

Also, as a club secretary said to me once—not so long ago, when I was arguing the point with him—"As long as doctors are *fools enough*" (the italics are mine) "to be got to work for next to nothing of course we will get them to."—I am, etc.,

Brewood Staffs, Feb. 18th.

FRANCIS J. GEOGHEGAN.

THE VACANT POLICE APPOINTMENT IN LIVERPOOL.

SIR,—Mr. Maxwell's letter in the JOURNAL of February 20th is perfectly accurate as far as it goes, but as it does not traverse any of the statements published in the JOURNAL of February 13th, it is not apparent why he wrote it at all. He has, however, omitted all reference to one important particular, namely, that within a year of the present medical officer to the B Division being appointed, at the close of 1895, at a salary commencing at £60 per annum, he (the medical officer) represented to the authorities that the salary was inadequate, and the authorities, recognizing the justice of his representation, forthwith raised the salary to £80 to commence, rising to £100 after five years' service. Will Mr. Maxwell explain for the benefit of your readers why, when making an authoritative statement, uninvited, in his official capacity, he chose to make no allusion to this important fact, and further, will he state the grounds on which "a commencing salary of £60, rising by increment of £20 to £80 after five years' service" is offered as an adequate salary now, whereas the Corporation declared by their action in 1896 that at that time the salary of the medical officer of the B Division ought to be £80, rising to £100 after five years' service?—I am, etc.,

Liverpool, Feb. 22nd.

A RATEPAYER.

The seventh Italian National Congress of Midwives will be held at Bologna in September next.

Medico-Legal.

ACTION FOR ALLEGED NEGLIGENCE.

At the Sussex Assizes at Lewes on February 19th and 20th, an action in which Mr. Stranger and his wife, of Shoreham, sued Dr. C. Rawdon Wood, of the same place, for damages for the alleged negligence of the defendant in his attendance on Mrs. Stranger as her doctor was tried before Mr. Justice Bucknill and a special jury. Mr. E. E. Humphrys and Mr. J. Flowers appeared for the plaintiffs; and Mr. W. P. G. Roxall, K.C., and Mr. H. C. Dickens, instructed by Messrs. Hempsom for the Medical Defence Union, for the defendants.

The statement of claim set out that the defendant, although knowing a miscarriage was feared, so negligently and unskillfully treated the female plaintiff that he failed to observe the significance of a discharge to which his attention was called, and that he failed to observe that she had miscarried, and continued to treat her afterwards as though she were still pregnant. Evidence having been called on both sides,

Mr. Justice Bucknill, in summing up, said that what the female plaintiff was entitled to from the defendant was such care and skill as was reasonable or ordinary in the profession. The jury must put aside the fact that the defendant was brilliantly qualified, because, in spite of that, he might yet be negligent. The jury must be absolutely sure that the plaintiffs had made out their case before they could find in their favour; if they had a doubt or anything short of positive certainty the defendant was entitled to their verdict. The jury, after a short retirement, gave a verdict for the defendant, and his Lordship said he heartily agreed; it was quite clear that there was no negligence. Judgement was entered accordingly for the defendant, with costs.

PARTNERSHIP AGREEMENTS.

A CORRESPONDENT writes that his partner, aged 70, has been away from his work on account of illness for the last four months, during which time he has personally done all the work. According to the partnership agreement, in the event of illness of either partner the other may employ a locum-tenent at the expense of the absent partner, and if the illness is of longer duration than three months, notice may be given to the invalided partner to retire, and after such retirement he may not practise within a radius of five miles for a certain number of years. He wishes to know: (1) Whether, as he did all the work himself, he is not entitled to deduct from his partner's share £12 10s. monthly for having done the work without a locum-tenent? (2) If a dissolution takes place, who is responsible for legal expenses? (3) Would he be acting too hardly in giving notice to his partner under the circumstances? (4) If a dissolution takes place, would his partner be justified in continuing to practise just outside the stipulated radius?

*. (1) Our correspondent is not entitled to deduct anything for the cost of a locum-tenent not employed. (2) Each party should pay his own legal expenses. (3) If his partner is not willing to make any allowance to him for the extra work entailed by the illness, he is justified in exercising any rights he possesses under the partnership agreement. (4) After a dissolution the retiring partner would be entitled to practise outside the prescribed area.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

PUBLIC HOSPITALS AND PRIVATE NURSING.

THE Honorary Secretary of the Division in which the hospital referred to under this head last week is situated informs us that the circular letter was sent only to medical men in the neighbourhood, and that the error in its issue was that a rumour had got about that probationers were sent out from the private nursing staff.

CANVASSING FOR A MEDICAL AID SOCIETY.

P. M. G.—It is impossible for us to say what view the General Medical Council might take of the facts if a case were brought before it. The description our correspondent gives suggests that the company is sailing very near the wind, and that a charge of canvassing for the benefit of the three medical officers might be established.

CLUB VACANCIES.

STORAX writes that a medical neighbour has recently died leaving no widow or any one dependent on him. He wishes to know whether it would be in order "to approach one of the clubs lately held by the deceased with a view of succeeding him."

*. If the practice of the deceased is in the hands of his executors to dispose of for the benefit of his representatives, it would be more in accordance with medical ethics for our correspondent to wait till he was approached by the club, or an advertisement was issued for a successor.

Obituary.

JOHN LINDSAY STEVEN, M.D., F.F.P.S.G.,

PHYSICIAN TO THE WESTERN INFIRMARY, GLASGOW.

THE sudden death of Dr. John Lindsay Steven, on February 14th, came as a great shock to the medical world. It was known that he had been confined to the house for a few days, but no serious condition was suspected. Indeed, up to ten days before his death he had been actively engaged in clinical teaching at the Western Infirmary, but on February 11th he complained of feeling unwell, and absented himself from his infirmary work. Even then, however, he did not consider his illness serious, and refused medical assistance. Towards the end of the week he became acutely ill, and was found to be suffering from pericarditis, which had been added on to an old-standing though apparently unsuspected nephritis. The remedies tried unfortunately brought no relief, and early on Sunday he died.

At the time of his death he was in his 51st year. His father was a shipbuilder in Glasgow, and in due course the son went to the university. His college career was a long record of success, and on graduating in 1880 he headed the honours list, and was awarded the proud distinction of being the first recipient of the Brunton Memorial Prize, which is allotted annually to the most distinguished graduate in medicine.

Almost immediately after completing his terms as House-Surgeon and House-Physician in the Western Infirmary he was appointed University Assistant to the Professor of Clinical Medicine, and occupied this post for eight years, thus serving his apprenticeship as a clinical teacher under the late Sir Thomas McCall Anderson.

He early showed a fondness for pathological investigation, and for eight years he assisted the late Professor Coats during the summer session, in addition to doing clinical work in the wards. He was, therefore, well qualified in pathology when in 1890 he received the appointment of Pathologist to the Royal Infirmary, and became Professor of Pathology in St. Mungo's College. In addition, the University Court made him Lecturer on Pathology to the women students. The dual appointment brought with it much work, as he had to deliver two lectures each day.

But even when actively engaged as a pathologist Dr. Steven did not abandon clinical work. Since 1889 he had been attached to the dispensary staff of the Royal Hospital for Sick Children. In 1885 he was appointed to the dispensary staff of the Royal Infirmary, and continued to hold this position for ten years. After seven years of the arduous work as pathologist he was elected by the managers of the Royal Infirmary to be one of the Visiting Physicians. He then gave up pathology and devoted himself entirely to clinical work. He did not long sever his connexion with the university, as he was soon afterwards appointed Lecturer in Medicine to the women students at Queen Margaret College. He maintained the lectureship till 1903, when he gave it up on being appointed to represent the Faculty on the General Medical Council.

His success as a clinical teacher was great, and when, on the death of Dr. James Finlayson, he applied for the vacant wards in the Western Infirmary he was unanimously elected. During the short time for which he held office in the Western Infirmary he more than maintained his reputation as a clear and successful clinical teacher. He soon attracted large clinics, and during his last session he had the second largest medical clinic. He had a great power of organization, and, as his teaching was based on an extensive and accurate knowledge of pathology, he was able to marshal his facts in a clear, convincing way, which made his lectures models of lucid exposition.

During his career, Dr. Steven occupied a very prominent position in local medical affairs. He became a Fellow of the Faculty of Physicians and Surgeons in 1889, and soon became an important member of that corporation. Since 1894 he had been a Member of the Council of the Faculty. After serving a number of years on the Library Committee in 1901, he succeeded the late Dr. James Finlayson in the position of Honorary Librarian. In 1903 it fell to the

Faculty to elect a new representative to the General Medical Council, and, after a keen contest, the choice fell on Dr. Steven. Previous to this he had acted for seven years as one of the Representatives of the Faculty on the Committee of Management of the Scottish Conjoint Board. He was also very prominent in the local medical societies, and in 1905 was elected President of the Glasgow Medical-Chirurgical Society, and in the following year occupied a similar position in the Pathological and Clinical Society.

He acted as Examiner in Pathology and in Medicine at the University of Glasgow, and in Pathology at the University of St. Andrews. Recently he was an applicant for the Chair of Practice of Medicine in the University of Glasgow, and in support of his candidature submitted strong testimonials from many of the leading authorities in medicine. Throughout his whole professional career Dr. Steven was a prolific contributor to medical literature. He published an excellent work on *Practical Pathology* in 1887, and in 1892 wrote a book on *The Pathology of Mediastinal Tumours*, and in 1900 published his *Lectures on Clinical Medicine*. For eleven years he was joint editor of the *Glasgow Medical Journal*. His numerous contributions to that journal ranged over the whole field of medicine. In his application for the Chair of Practice of Medicine he was able to quote 102 articles contributed to various periodicals. Among the most important was that which in 1884 he submitted for his thesis for the M.D. degree. This work on the pathology of suppurative inflammations of the kidney attracted considerable attention, and obtained high commendation—the highest award conferred by the university.

Dr. Steven was a man of strong convictions. He was a lifelong abstainer and was keenly interested in anything connected with the movement in favour of temperance, and frequently appeared on public platforms as an advocate of total abstinence. His convictions sometimes brought him into conflict with those of others, but Dr. Steven enjoyed the warm respect of all who came into contact with him. He was a transparently honest man, and freely gave of his very best in whatever he attempted. He was an enthusiast and never spared himself. To those under him he was invariably kind and considerate. His loss will be deeply felt throughout Scotland. He was a man of wide learning, and enjoyed a well-deserved and well-founded reputation as a scientific physician.

Throughout his whole life he was a strenuous worker, and it seems cruel that he should have been taken away at the very time when he had attained the highest position in his profession and was about to enjoy the well-merited reward which his hard work had entitled him to. In him the West of Scotland loses a worthy representative, with an enthusiasm for his profession and a thorough knowledge of all questions and principles relating to it.

CHARLES HENRY FELIX ROUTH, M.D.LOND.,

M.R.C.P., M.R.C.S.

CONSULTING PHYSICIAN TO THE SAMARITAN FREE HOSPITAL.

THIS veteran physician, who qualified for practice sixty-six years ago and had been a Doctor of Medicine of the University of London for sixty-four years, died on Friday last at the advanced age of 87. C. H. F. Routh was born in Malta on January 4th, 1822, during the residence there of his father, Commissary General Sir Randolph Routh, K.C.B., whom he subsequently accompanied to Canada, where he began his education. It was not until his fifteenth year that he came to England. He entered as an arts student at University College, London, and in 1840 joined the medical faculty, so that at the time of his death he had been associated with medicine for nearly seventy years. In those days C. J. B. Williams, Anthony Todd Thomson, W. H. Walshe, Murphy, and the great Liston were his teachers. Amongst other prizes at the medical school, he obtained the Fellowes gold medal for essays in clinical medicine, which were published in the *Medical Gazette*, 1845-50. He qualified as M.R.C.S. in 1843, and graduated M.B.Lond. with honours in 1844, gaining the degree of M.D. a year later. He held several resident appointments, and when obstetric house-physician to Dr. Murphy he found that his tastes naturally inclined to obstetrics and diseases of women.

Routh studied for some time in the hospitals of Paris, Prague, and Vienna, and in the Austrian capital he became

associated with that great obstetrician Ignaz Philipp Semmelweis, whose researches, whose struggles, and whose quarrels played so prominent a part in conferring an inestimable boon on womankind—the establishment of aseptic midwifery in lying-in hospitals. Semmelweis was junior obstetrician in the General Hospital at Vienna under a perfunctory medical officer, Professor Klein, and the mortality was appalling. Patients on finding themselves among the inmates of the dreaded clinic fell on their knees and with clasped hands begged to be allowed to return to their homes. We all know of the criminal carelessness which permitted students fresh from the adjacent *post-mortem* and dissecting rooms to examine women in labour, and of the relative immunity of the neighbouring midwives' clinic. We know also the inveterate obstinacy of the senior officer and of other physicians who would not agree to Semmelweis's self-evident propositions as to the cause of mortality in the students' clinic. The man who first vindicated Semmelweis in England was Routh. On November 28th, 1848, he read before the Royal Medical and Chirurgical Society a communication on the causes of the endemic puerperal fever in Vienna, to be found in the thirty-second volume of the Society's *Transactions*. Semmelweis was ever afterwards profoundly grateful to Routh, acknowledging his English pupil's enthusiastic support of his views in his work *Die Aetiology, der Begriff und die Prophylaxis des Kindbettfiebers*, published in 1861. Four years after this monograph appeared Semmelweis died insane, as ill-fated as were the first anaesthetists. His British advocate had many years of useful life before him. The whole narrative of Semmelweis and his labours, and the support he gained from Routh in this country, is chronicled by Dr. Schütter von Waldheim in his work—*Ignaz Philipp Semmelweis, Sein Leben und Wirken*, issued in 1905.

In 1855 Routh was elected Assistant Physician to the Samaritan Free Hospital, together with Dr. J. S. Stocker and Dr. Graily Hewitt. That institution had been founded a few years previously by Dr. William Jones and Henry Savage. For many years, when he became full Physician, Routh attended the Dorset House Branch of the Samaritan Hospital, where vaginal and perineal operations were performed, the old Lower Seymour Street building being reserved for Spencer Wells's ovariectomies. Before Routh joined the hospital in 1855 he had been for a few years in general practice, but, becoming private assistant to his former teacher, Murphy, he ultimately decided to develop as a specialist. Routh was one of the founders of the Obstetrical Society of London; he spoke at its inauguration on December 16th, 1858, was elected at once member of council, and was fated to be, with Drs. Lloyd Roberts and Riallmark, one of the three original Fellows who survived that society when it became, in 1907, a section of the Royal Society of Medicine. It was then fused with the British Gynaecological Society, of which Routh was also an original Fellow. He took an active part in discussions and papers at both these societies, and in the Medical Society of London he was Orator in 1859 and Lettsomian Lecturer in 1864, when the subject he chose was the pathology, differential diagnosis, and treatment of fibrous tumours of the uterus. In 1875 he became President.

The best known of Routh's works published independently of societies is *Infant Feeding and its Influence, or the Causes and Prevention of Infant Mortality*, first

published in 1860; it ran through three editions, and was also issued in the United States and translated into foreign languages. Routh was associated with several philanthropic institutions, and received honorary titles from foreign learned societies.

Recently Dr. Routh suffered from the infirmities of age; he was attended in his last illness by Dr. C. Theodore Williams. He leaves a widow, to whom he had been married fifty-six years, two daughters, and three sons, two of whom, Dr. Amund Routh, Obstetric Physician at Charing Cross Hospital, and Mr. Randolph Routh, Surgeon to the Bridgewater Infirmary, are members of their father's profession.

Dr. Routh was interred in Kensal Green Cemetery on Tuesday, February 23rd, after a memorial service had been held at St. Paul's, Portman Square, at which several of his colleagues were present, as well as the inmates of the Cripples' Home for Girls, to which institution he was Consulting Physician.

GEORGE EDWARD WALKER, F.R.C.S. ENG.,

SENIOR HON. SURGEON, ST. PAUL'S EYE AND EAR HOSPITAL, LIVERPOOL.
We regret to announce the death of Mr. George Edward Walker, F.R.C.S., which took place at Las Palmas, Grand Canary, on February 15th.

George Edward Walker was born in Wigan in 1839, and was educated at Wigan Grammar School and at Chester. In 1859 he entered University College Hospital, London, and obtained the diploma of L.S.A. in 1862 and of M.R.C.S. in 1863. After holding resident appointments at University College Hospital, the Brompton Hospital for Consumption, and the Manchester Royal Infirmary, he obtained the Fellowship of the Royal College of Surgeons of England by examination in 1869.

While in London he was attracted to the study of diseases of the eye, and worked for some time at the Royal London Ophthalmic Hospital, Moorfields, where he was clinical assistant to Sir William Bowman. On settling in Liverpool in 1870 he began a general surgical practice, but while waiting for a vacancy on the staff of one of the hospitals he took two small rooms in St. Paul's Square for the gratuitous treatment of the poor suffering

from diseases of the eye or ear. The work grew rapidly, and soon, with the help of his father-in-law, the late Mr. William Nimmo, and others, the house was taken and turned into a public charity under the name of St. Paul's Eye and Ear Hospital. When the next vacancy occurred on the staff of one of the general hospitals he found that, as the only candidate holding the Fellowship, he was likely to be elected, but that under its rules he would not be allowed to hold two honorary hospital appointments. He was strongly tempted, therefore, to abandon his post at the newly founded hospital, but he refused to desert the committee who had shown their trust in him by founding St. Paul's Hospital, and he withdrew his candidature. He was rewarded by seeing St. Paul's Hospital, during his thirty-eight years' work there, grow from its small beginnings into a hospital of 50 beds, with a yearly attendance of nearly 10,000 patients. His heart was in his hospital work, and with the exception of brief holidays, he visited the institution daily until towards the end of last year, when ill-health compelled him to go abroad.

Other appointments which he held at the time of his death were those of Honorary Surgeon to the School for the Indigent Blind, and Honorary Consulting Ophthalmic

GEORGE EDWARD WALKER.

Surgeon to the David Lewis Northern Hospital. He was also sometime Honorary Ophthalmic Surgeon to the Royal Albert Edward Infirmary, Wigan; Honorary Surgeon to the Hospital for Skin Diseases, Liverpool; and Surgeon to the Southport Convalescent Home. He held the office of Vice-President of the Liverpool Medical Institution, and also that of Vice-President of the Lancashire and Cheshire Branch of the British Medical Association.

Always an original thinker, he disregarded fashion in surgery, and was often in advance of his time. He was one of the earliest advocates, if not the first, of the immediate ligation of the common carotid artery in intracranial aneurysm of the internal carotid; and in his book, *Essays in Ophthalmology*, published in 1879, he recorded a case successfully operated on in 1878. He wrote further on this subject in a paper on pulsating exophthalmos, in the *Ophthalmological Transactions*, 1887, and the *Lancet*, 1894; and in an address on Pulsating Exophthalmos, a Plea for Early Ligation, he recorded (with Mr. Chauncy Pacey) three more cases. He was a strong advocate of the free use of mercurial inunction in all deep inflammations of the eye, and recorded several remarkable cases of its efficacy in sympathetic ophthalmia.¹

He worked hard in his spare time at the physiology and pathology of the eyes, often rising at dawn to work at the microscope, and advanced original theories, founded on his observations, on accommodation and on glaucoma in his articles on the function of the ciliary body, *Lancet*, 1885, and on glaucoma.² He had a great respect for the iris, and was a constant opponent of indiscriminate iridectomy; in glaucoma he preferred his own operation of hyposepheral cyclotomy, which he described in a paper in the *Ophthalmological Transactions*, 1884. He devised operations for the release of synchiae, both anterior and posterior, of the iris, and described the former in a paper in the *Lancet*, 1885, but the operation in which he took the greatest pride was that for corneal ulceration, described under the name of kerotomy in an article in the *Liverpool Medico-Chirurgical Journal* for 1889. His operations have stood the test of time and are in daily use in the practice of St. Paul's Hospital. Kerotomy, in particular, has proved a most successful operation in the treatment of corneal inflammation.

Mr. Walker was a man of the highest integrity, who, under a somewhat severe and brusque exterior, carried a warm heart filled with generous sympathies. His home life was an ideal one, and he was a true friend. He was deeply interested in the School for the Blind, and the afflicted inmates were always the objects of his tender solicitude. In him they have lost a friend who was ever foremost in defending them whenever they needed a champion.

He married in 1870 Louise, daughter of William Nimmo, cotton broker, of Birkdale, and leaves his widow, two daughters, and four sons, of whom one is in the medical profession, and has been his assistant for the past seven years.

A memorial service was held on February 23rd at the Church for the Blind, Liverpool, of which he had been a warden for many years, and an eloquent and appreciative address was delivered by the Chaplain, the Rev. T. W. M. Lund, who had been closely associated for many years with Mr. Walker, both in the School and the Chapel for the Blind.

HENRY E. CLARK, C.M.G., M.R.C.S., F.F.P.S.G.,

FORMERLY PROFESSOR OF ANATOMY, ST. MUNGO'S COLLEGE, GLASGOW.

The death from pneumonia, after a short illness, of Mr. Henry E. Clark, formerly Surgeon to the Royal Infirmary, Glasgow, has removed a man who was prominent in the medical life of that city, and whose loss is felt by many as a personal bereavement.

Henry E. Clark was born at Wootton, in Warwickshire, in 1845, and received his early education in the Grammar School at Stratford-on-Avon. His medical studies were carried on in the old Andersonian University of Glasgow, and he took the Scottish Conjoint Diploma in 1870. One year later he became a M.R.C.S.Eng., and five years later joined the Faculty of Physicians and Surgeons of Glasgow. After acting as Resident Physician and

Surgeon he became attached to the Royal Infirmary as Dispensary Surgeon, and was appointed also to the Eye Infirmary as Assistant Surgeon. In due course he was promoted to full Surgeonships in both these institutions, but became more particularly associated with the Royal Infirmary, in which he served as Surgeon until he retired in 1906 on account of the age limit.

In the earlier stage of his career Mr. Clark was well known as a teacher of anatomy. He was appointed Lecturer on Anatomy in the old Glasgow Royal Infirmary Medical School in 1876, and taught that subject there as first Professor of Anatomy after it became the St. Mungo's College some twenty years ago. In 1892 the Surgery Chair in St. Mungo's College fell vacant, and at his request he was transferred to the vacant post, and commenced to lecture on surgery. This post he held with much acceptance until he retired under the age limit.

Mr. Clark made numerous contributions to medical periodicals, and edited the ninth, tenth, and eleventh editions of Wilson's *Anatomists' Vade Mecum*, one of the most popular students' textbook of its time. For some time he also edited the *Glasgow Medical Journal*.

He took great interest in the local medical societies, and was a constant and enthusiastic attendant, and frequently took part in debates. At various times he occupied the post of President in the three chief medical societies of Glasgow. He also filled with great acceptance the position of President of the Faculty of Physicians and Surgeons from 1903 to 1905.

At the time of the South African war he was requested to go out and take medical charge of the Scottish National Red Cross Hospital, which on its arrival at the seat of war was dispatched at once to Kroonstad, Orange River Colony. This hospital was the first medical assistance to reach this place after the town had been taken by Lord Roberts. The hospital did a great deal of valuable work, and for his services Dr. Clark was mentioned in despatches. On returning home he was gazetted C.M.G. Among other honorary posts which he held was that of Honorary Associate of the Order of St. John of Jerusalem, and in 1905 he was elected an Honorary Fellow of the Royal College of Surgeons of Edinburgh.

WILLIAM PARSON, M.R.C.S., M.S.A.,

GODALMING.

THE death on February 8th, in his 75th year, at his residence in Godalming, of Mr. William Parson will be the cause of great regret to a large number of friends and old patients. He was the third generation of the same family who occupied the house in which he died, the practice having been originally founded by his grandfather. He received his early education at St. Paul's School, Portsmouth, and afterwards entered the medical faculty of University College; he was a resident pupil with the late Sir William, then Dr. Jenner, and this association led to a lifelong intimate friendship. He obtained the diploma M.R.C.S. in 1855, and that of L.S.A. in 1856. He then held for some time the appointment of house-surgeon at the Hospital for Sick Children, Great Ormond Street, afterwards settling in Haslemere; in 1858, however, owing to his father's illness, which soon terminated fatally, he removed to Godalming, where he long enjoyed a large private practice. He was the first medical officer of health for Godalming and the neighbouring part of the county, a post which he held for twenty-seven years. He was for twenty-eight years Medical Officer to the Hambledon Union Workhouse, and Public Vaccinator, and was for some years Deputy Coroner for West Surrey. He entered the Town Council of Godalming in 1864, and in 1866 served the office of Mayor. Subsequently he was nominated Justice of the Peace for the borough. He took keen interest in the affairs of the Society of Apothecaries of London; having served as Junior and Senior Warden, he was elected Master in 1902-3, and, after passing the chair, maintained his interest in the affairs of the society, insisting upon attending meetings, even in inclement weather, at no slight risk to his health. Failing health induced him very largely to diminish his work in 1900, and shortly afterwards he retired altogether from practice.

Mr. Parson gave the whole of his energy to his profession, never shirking any call made upon him, though it might be at the loss of his own health and comfort. He

¹ *Ophth. Trans.*, 1884.

² *Ibid.*, 1887.

was a typical example of the high-principled, conscientious, kind-hearted, self-sacrificing country doctor, to whom the public owe so deep a debt of gratitude. His goodness to the poor was continuous and unassuming, and he was held in high esteem by rich and poor alike. He leaves a widow and two daughters to mourn his loss. The funeral, which took place at Godalming parish church on February 12th, was attended by the Mayor and other members of the Corporation, by many members of the profession, as well as numerous other friends, including representatives of the Society of Apothecaries.

THOMAS CARLYLE PARKINSON, M.D. (SYDNEY).

Born in this country and in his native land, Australia, the friends of Dr. Thomas Carlisle Parkinson will hear with deep regret of his untimely death, which occurred on February 4th.

Dr. Parkinson had recently been appointed a member of the Commission for the Investigation of Plague in India, and was working at the isolated laboratories at Elstree, placed at the disposal of the Commission by the Lister Institute. He was engaged upon an experimental inquiry into protective inoculation against plague, and in the course of his experimental work he unfortunately contracted an accidental infection, and died after a short illness from pneumonic plague.

Dr. Parkinson's death terminates a career which gave every promise of great distinction. He started his medical studies in 1901 at the University of Sydney, New South Wales, and in each of the five years of his course he gained first class honours and the premier place. He graduated in 1906, and was awarded the university medal for special distinction. During his undergraduate career he also obtained the Renwick Scholarship for Natural Science and Comparative Anatomy and the John Harris Scholarship for Anatomy and Physiology. In 1906 he held the position of Resident Medical Officer to the Royal Prince Alfred Hospital, Sydney; in 1907 he was Resident Pathologist to the same hospital, and in 1908 was for a time Junior Medical Officer at Callan Park Hospital for the insane.

Dr. Parkinson early showed his bent for scientific investigation, and both as a student and during his post-graduate work at Sydney contributed several papers to the *Journal of the University of Sydney Medical Society*. In April, 1908, he was awarded the James King Travelling Scholarship and came to this country to continue his studies, and worked at the Lister Institute until October, when he was appointed to a position on the Indian Plague Commission.

Dr. Parkinson was possessed of an amount of reserve which prevented him from making friends quickly. His acquaintances will remember him as a keen worker, but his comrades realize that they have lost a good and trusted friend. He lost his life striving in the interests of others, doing a man's work as a man should.

We have to record with much regret the death of Mr. ALFRED TEMPLE SPANTON of Birkenhead. Mr. Spanton was ill for a few days only, death being due to heart failure following pneumonia. He was the eldest son of Mr. W. D. Spanton, F.R.C.S., of Hanley, consulting surgeon to the North Staffordshire Infirmary, and for many years a member of the Central Council of the British Medical Association. Mr. Alfred Temple Spanton, who had just completed his 33rd year, was educated first at Cheltenham College, and then at Trinity College, Cambridge, where he graduated B.A. with honours in 1897, and M.A. in 1902. After commencing his medical education as a pupil at the North Staffordshire Infirmary, and also as a student at Addenbroke's Hospital, Cambridge, he entered the medical school of St. George's Hospital. He took the diploma L.S.A. in 1900, and that of L.R.C.S. Edin. in 1905. He was for some time Resident Surgeon at the Leeds Dispensary, and subsequently Resident Medical Officer at the Hulme Dispensary, Manchester. He began to practise in Birkenhead about eighteen months ago, and being thoroughly trained in his profession, and a man of gentle disposition, conscientious, and painstaking in everything he did, would undoubtedly have attained success had his life been spared. The funeral, which took place on

February 18th, afforded an opportunity for many tributes of respect to be paid by friends and patients. In the Potteries, where Mr. W. D. Spanton is so well known, great sympathy is felt both with him and with his family in his sad bereavement, and this feeling will be shared by all members of the Association who have had the advantage of knowing Mr. Spanton.

Universities and Colleges.

UNIVERSITY OF LONDON.

APPOINTMENT OF A ROYAL COMMISSION.

The King has been pleased to appoint a Royal Commission on the subject of university education in London.

The terms of the reference are:

To inquire into the working of the present organization of the University of London, and into other facilities for advanced education (general, professional, and technical) existing in London for persons of either sex above secondary school age; to consider what provision should exist in the metropolis for university teaching and research; to make recommendations as to the relations which should in consequence subsist between the University of London, its incorporated colleges, the Imperial College of Science and Technology, the other schools of the University, and the various public institutions and bodies concerned; and further, to recommend as to any changes of constitution and organization which appear desirable. In considering these matters, regard should also be had to the facilities for education and research which the metropolis should afford for specialist and advanced students in connexion with the provision existing in other parts of the United Kingdom and of His Majesty's Dominions beyond the Seas.

The Chairman of the Commission is the Right Hon. R. B. Haldane, K.C., M.P., and the members are:

The Right Hon. Viscount Milner, G.C.B., G.C.M.G.

The Right Hon. Sir Robert Romer, G.C.B.

Sir Robert L. Morant, K.C.B.

Mr. Laurence Currie, M.A.

Mr. W. S. M. Cornick, M.A., LL.D.

Mr. E. B. Sargent, M.A.; and

Mrs. Creighton.

The Joint Secretaries to the Commission are Mr. J. Kemp and Mr. H. F. Heath.

Mr. Haldane, it will be remembered, was chairman of the committee the report of which led to the establishment of the Imperial College of Science and Technology, and is not merely a politician who has shown an interest in science, but a statesman who is also a man of science. He has consistently supported the new university movement in England, and has shown particular interest in the organization of university teaching in Liverpool and Bristol; of the needs of London he gained some special experience while holding for two years the office of Vice-president of the University College.

Viscount Milner, who during his long and distinguished career as Under Secretary for Finance in Egypt, as Chairman of the Board of Inland Revenue, and as High Commissioner for South Africa, has displayed remarkable powers as an organizer, gave particular attention to educational problems while occupying the last-named office. He has a slight direct connexion with the University of London, for he was a student at King's College before proceeding to Oxford.

Sir Robert Romer, who was senior wrangler and Smith's prizeman in 1885, was for a short time professor of mathematics at Queen's College, Cork, before being called to the Bar. After holding a Chancery judgeship for nine years, he was for the next seven Lord Justice of Appeal, only retiring three years ago.

Sir Robert L. Morant, K.C.B., has been Permanent Secretary to the Board of Education since 1903.

Mr. Laurence Currie, M.A., is a member of the banking firm of Glynn, Mills, Currie and Co.

Mr. W. S. M. Cornick, M.A., LL.D., Secretary to the Carnegie Trust for the Universities of Scotland, was at one time Professor of English in University College, Dundee.

Mr. E. B. Sargent, M.A., was Educational Adviser to Lord Milner in the Transvaal.

Mrs. Creighton, who is the widow of the late Bishop of London, and herself a historian of distinction, has, no doubt, been appointed in consideration of the large number of women undergraduates and graduates of the University of London.

Of the joint secretaries, Mr. J. Kemp is a barrister having some experience in London government, and Mr. H. F. Heath, formerly Academic Registrar of the University, is now Director of Special Inquiries and Reports to the Board of Education.

DEGREES.

The following candidates passed the Preliminary Scientific Examination for internal and external students, January, 1909, in the subjects indicated:

PART I: INORGANIC CHEMISTRY, EXPERIMENTAL PHYSICS, AND

Inorganic Chemistry and Experimental Physics.—P. A. Dargan, King's College; F. R. Fletcher, London Hospital; S. A. Forbes, London Hospital; H. L. G. Foxell, University College; L. Kingston, King's College; E. D. Lindow, King's College;

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL
The offices of the British Medical Association and of the
BRITISH MEDICAL JOURNAL are at 429, Strand, London.

Queries, answers, and communications relating to subjects
to which special departments of the BRITISH MEDICAL JOURNAL
are devoted will be found under their respective headings.

QUERIES.

FOREST asks for a respectable home for a woman about 67
years of age who has cardiac disease but is able to go out.
A year or more has elapsed since she had a bad attack;
10s. 6d. to 12s. 6d. per week could be paid.

A CASE FOR DIAGNOSIS.

B.S. asks for advice in the treatment of a man, aged 35, who
has for seven years suffered from acute colicky pains and
slight abdominal distension, the attacks terminating with the
passage of large quantities of flatus. About four years ago
the appendix was removed, as the attacks were attributed to
appendicular colic; nothing abnormal was then found in the
abdomen. He still has an acute attack about every ten days,
lasting for about twenty-four hours, but is seldom really free
from pain. The attacks, which appear to be growing worse,
are not accompanied by diarrhoea or constipation, and he
passes little mucus—certainly not enough to justify the term
mucous colitis.

BOOKS FOR POPULAR LESSONS.

B. wishes to know of a suitable book or books dealing with
scientific subjects in a popular style, and suitable for
addresses to men attending Sunday morning adult school.

For the purpose of series of addresses to be developed to
a men's Sunday school we think the following would prove
useful: *Physiography: An Introduction to the Study of Nature*.
By T. H. Huxley. Revised by R. A. Gregory. 1904. 4s. 6d.;
Sir Robert Ball's *Story of the Heavens* (London: Cassell and
Co. 1893. 10s. 6d., but which can be obtained in sixpenny
parts); and Lord Avebury's (Sir John Lubbock's) books on
Ants, Bees, and Wasps, etc. Also *The Body at Work*, by A.
Hill, M.A., M.D., F.R.C.S. (London: E. Arnold. 1908. 16s.).

ANSWERS.

AUSTRALIAN.—There are a good many country places in
England where a man might live with care and get his
children well educated on the income mentioned. Our
correspondent's best plan would be to return home and look
out for himself.

REFRACTION TEST CASES.

S. T. B.—The usual full-size case for work contains
double sets of spheres, + and —, in quarters for 0.25 to 3.0,
then halves from 3 to 6, dioptres for 6 to 16, and two dioptres
for 16 to 20; cylindrical lenses, double sets, and + — in
quarters for 0.25 to 3.0, and halves for 3 to 6. Besides these
there are prisms, coloured glasses, diaphragms, etc., and
trial frames. All lenses should be mounted. Boxes containing
fewer lenses than those indicated are not to be recommended,
while unmounted lenses are constantly getting broken.

M.D. IN TROPICAL MEDICINE.

CAPTAIN I.M.S.—The scope of the paper in general medicine
at the examination for the degree of M.D. in Tropical Medicine
in the University of London is higher than that required
for the M.B. The candidate must pass in the paper on
general medicine as well as that on tropical medicine. The
practical examination is a searching one, on much the same
lines as the practical examinations at the tropical schools.
We believe that without a special course a candidate would
have little chance of success. Under certain circumstances
exemption may be obtained from a part or the whole of
the examination by presenting a thesis or published work
embodying an independent research in tropical medicine.
In addition to the works by Manson on *Tropical Diseases*,
Rogers on *Fevers in the Tropics*, Stephens and Christophers's
Practical Malaria, James and Liston's *Anopheles Mosquitos*,
and the second part of the second volume of *Albutt's System
of Medicine*, to which our correspondent refers, he might con-
sult the following: Scheube's *Diseases of Warm Climates*, trans-
lated by P. Falke, edited by J. Cantlie, F.R.C.S., second
edition (London: J. Bale, Sons, and Danielsson. 1903. 30s.);
Daniels and Stanton's *Studies in Laboratory Work*, second
edition (London: J. Bale, Sons, and Danielsson. 1907. 16s.);
Simpson's *The Principles of Hygiene in Tropical and Sub-
tropical Countries* (London: J. Bale, Sons, and Danielsson,
1908. 15s.); Hewlett's *Manual of Bacteriology*, third edition,
(London: J. and A. Churchill. 1908. 10s. 6d.); Emery's *Clinical
Bacteriology and Haematology*, third edition (London: H.
K. Lewis. 1908. 7s. 6d.); Theobald's *Monograph of the Culi-*

cidæ of the World (London: Longmans, Green, and Co. 1903.
21s.); and Austen's *Monograph on the Tsetse Flies* (London:
British Museum Natural History. 1903. 15s.).

LETTERS, NOTES, ETC.

X-RAY TREATMENT OF VENEREAL SORES.

MR. C. F. MARSHALL (London, W.): With regard to the treat-
ment of venereal sores by the x rays, described by Major
French in the BRITISH MEDICAL JOURNAL of February 20th,
I may mention that a case of severe phagedenic chancre
(syphilitic) was brought to me a few days ago after treatment
by the x rays. The patient had seven exposures in the course
of two weeks. In this case the phagedenic had destroyed a
considerable portion of the glans penis and had caused a
urethral fistula behind the glans. As mercurial and local
treatment was producing no effect, the x rays were recom-
mended by another surgeon. The only result was to cause
some increase in the pain; there was no effect on the
phagedenic process whatever. Considering that venereal
sores, whether phagedenic or not, usually yield to simpler
methods of treatment, I think that the use of such a ther-
apeutic agent as the x rays—the action of which is even now
little understood, and the effects of which are often uncertain
and sometimes harmful—in these conditions is contra-
indicated.

DR. H. D. McCULLOCH (London, W.) writes: In the note appear-
ing under "Memoranda," p. 464, of the BRITISH MEDICAL
JOURNAL of February 20th, Major H. C. French remarks that
he has no knowledge of x rays having ever been used in the
above class of cases. I beg leave to refer Major French to an
abstract in the EPITOME of the JOURNAL of February 16th,
1907, Paragraph 89: also to a paper contributed by me in the
JOURNAL of October 17th last, in which an attempt was made
to elucidate the bio-chemical action resulting in the induction
of a specific immunity when the x rays are caused to influence
the lymphoid or lymphatic structures which are functionally
involved.

MEDICAL FOOTBALL.

COLD weather during the past week prevented the playing of
any medical fixtures of importance. Among the matches
postponed was that between Middlesex and St. Thomas's
which was to have been replayed last Monday. The following
table shows the positions of the various hospitals in the Cup
Tie:

First Round.	Second Round.	Semi-final.	Final.
1.—London St. Mary's, London			
2.—Charing Cross University	Charing Cross	London	Guy's
3.—Guy's Westminster	Guy's†		
4.—Middlesex St. Bartholomew's	Middlesex†	Winner†	Winner
5.—St. Thomas's King's College	St. Thomas's		

Scratched. † A bye.
: This match, played and drawn, to be replayed on March 1st.

The Prince of Wales was present on Wednesday at the
Richmond Athletic Ground, when the London Hospital met
Guy's, to fall to the latter by a goal and a try (8 points) to
nothing. The captains of the fifteens, Mr. L. B. Stringer
(Guy's) and Mr. J. M. Mehaffey (London) were presented to
His Royal Highness, and the teams lined up and gave three
hearty cheers. Excellent play on the part of both hospitals
followed, and Guy's victory was due to superior organization.
Their backs played a splendid game, and to Stringer in the
three-quarter line the first score was due. Batchelor, the
London back, had relieved with a punt far down the field,
only for the ball to fall into Stringer's hands. As soon as he
got in his kick he followed up keenly, and, relying on his
speed, retrieved the ball and raced over the line. During the
second half Guy's were hard pressed and owed their immunity
to the brilliant defensive play of their backs, who, by a master-
piece of combination, scored a clever try, Stokes touching
down about five minutes before time. The final will be
played between Guy's and the winners of Middlesex and
St. Thomas's.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£ s. d.
Eight lines and under	0 4 0
Each additional line	0 0 6
A whole column	2 13 4
A page	8 0 0

An average line contains six words.

All remittances by Post Office Orders must be payable to the
British Medical Association at the General Post Office, London.
No responsibility will be accepted for any such remittance not so
safeguarded.

Advertisements should be delivered, addressed to the Manager,
429, Strand, London, not later than the first post on Wednesday morning
preceding publication; and, if not paid for at the time, should be
accompanied by a reference.

N.B.—It is assumed that the rules of the Post Office to receive letters at
Postes Restantes addressed either in initials or numbers.

An Address

ENTITLED

SOME CLINICAL FACTS REGARDING MAMMARY CANCER.*

BY

SIR HECTOR C. CAMERON, M.D., C.M., F.F.P.S.G.,
PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF GLASGOW.

GENTLEMEN,—I am very sensible of the great honour you have done me by inviting me to address you, but now, when I begin the task, I feel that many of you may be disposed to regard the subject which I have chosen as a somewhat trite and threadbare theme. It is true that worldwide attention is being devoted at present to all considerations regarding cancer, in the hope of its real cause being discovered, as has already been done in comparatively recent years in the case of tuberculosis, osteomyelitis, and many other infective diseases. In this respect the whole medical world is on the tiptoe of expectation. The researches conducted, however, largely concern the pathological aspects of the subject, and you will agree with me when I say that, in the investigation of any disease, fundamental and important truth is best sought by considering the results of pathological study along with the facts of clinical observation. Neither department of work is self-sufficient; each tends more or less to explain, sometimes to confirm or to refute, inferences drawn from the other. While, therefore, pathologists are hard at work, it is equally incumbent upon those whose experience has been wide to make known in some way such facts of that experience as may appear important, even although they may not be new. What has impressed itself upon the observation of one who, during a long and busy professional life, has always had under his care patients suffering from mammary cancer may at all events, I hope, arouse some interest in the minds of those of you whose familiarity with that disease has been neither so long nor so constant.

The present clinical teaching in regard to cancer of the breast may, I think, be fairly summarized thus: It is a disease which probably invades the body from without, and is at first strictly of local character and of local consequence. If removed at a very early stage—that is, when the tumour is recent and still small—by an extensive operation definitely planned and carried out, a satisfactory cure may follow. Should no return of the disease occur within a period of a few years—say three to five—this result may be considered as fairly assured.

To the general tenor of such doctrine no one is now likely to offer any great objection; but, at the same time, as I shall endeavour to show, experience proves that many of these statements are contradicted, from time to time, by the progress and issue of individual cases. The disease is one of the most contradictory of all diseases. In almost all respects there is apt to be want of uniformity in the behaviour of different cases, even when they strongly resemble each other in the first instance. These statements I shall endeavour to substantiate, entirely by reference to clinical experience.

CASE I.

In the end of July, 1900, Mrs. E., a lady 67 years of age, was sent to consult me by Dr. Sinclair of Bo'ness in regard to a small, rounded and hard lump under the pectoral muscle at some distance below the right clavicle.

History and Operation.

Twenty-seven years previously the right breast had been removed, when she lived at Berwick-on-Tweed, by Dr. Philip MacLagan and Dr. Allan Jamieson, on account of a hard growth which it contained. It was evident from the size and situation of the scar that the axilla had not been interfered with. Dr. Allan Jamieson (now of Edinburgh) has informed me that he remembers this patient's case well, and although he cannot recall whether any histological examination of the tumour was made after its removal, he can say that no doubt existed in their minds at the time that they were dealing with a cancer. The present little growth lay, as I found when I removed it, under the pectoral muscle and much nearer to the scar than to the clavicle. It was very movable, but on incising the skin

I found it was slightly attached to the under surface of the muscle, and so I removed a considerable portion of the muscle with it. The cellular tissue around it was quite loose, and I lifted out the growth with my fingers passed beneath it. I could feel no other nodule and no enlargement of axillary glands. Whether wisely or not, I contented myself with the removal of the growth, leaving the armpit still untouched. The growth was about the size of the distal phalanx of a finger, and had been growing since it was first noticed by the patient nine months before. It was very firm but not extremely hard.

Histological Examination of Tumour.

A histological examination of it was made by my friend Dr. A. R. Ferguson, at that time assistant to Professor Muir of our university, and now Professor of Pathology in the Government School of Medicine at Cairo, and he reported as follows:

"Ladly, aged 67. Amputation of mamma twenty-seven years ago for cancer (?). The nodule of tumour tissue in the situation of mamma proves malignant. It is so richly cellular as to cause difficulty at first sight in diagnosis between carcinoma and sarcoma. I believe it, however, to be carcinomatous."

After-History.

On inquiry recently made, I find that Mrs. E. survived my operation about five and a half years. Under date December 9th, 1908, her son-in-law, with whom she resided, writes, regarding her illness and death: "As far as we know, the disease did not reappear. The nurse told us that Mrs. E. spoke about a lump somewhere, but the information was not sufficient for us to say anything about it. She died two years ago from congestion of the lungs." I have since also heard from the medical man who attended Mrs. E. in her last illness—in the neighbourhood of London where she latterly lived. He states that he "occasionally but rarely saw her chest, as she had the greatest objection to any examination of the scars." "I think," he adds, "I should have found the suspected cancer had it been present to any extent."

It is possible that the chest ailment which proved fatal in the old lady's case may have been due to cancer, but, in the absence of *post-mortem* examination, one must remain in doubt.

Now let us consider what lessons may be learned, what speculations may reasonably be entertained, from reflections upon such a case as this one. And, first, let us ask, Is this late recurrence of cancer, nearly thirty years after the removal of the primary tumour, a fresh development of the disease and quite unconnected with the original growth, or was the nodule which I removed in 1900 an offspring of that contained in the breast amputated at Berwick-on-Tweed in 1873? In other words, Was the recurrence a reinvasion or a residue? The very long period of absolutely good health and freedom from any new sign of the disease is apt to make any one, who has not had repeated experiences of late recurrence, at once conclude that the fresh outbreak is an independent and new invasion. What is more likely than that a woman who has been affected by this disease at 40 years of age, and has been, as we think, completely cured, should again develop it before she ends a long life? It would not surprise us if one of her sisters or daughters were to become affected with the disease, and why not herself, who has already proved her proneness in that direction? That we do occasionally meet with examples of cancer arising a second time in the same individual, and where its later has clearly no relation at all to its earlier manifestation, no case could better illustrate than the following:

CASE II.

On September 28th, 1896, Mrs. B., aged 44, was admitted under my care in the Western Infirmary of Glasgow with a hard tumour of the right breast, and a few days afterwards I removed the breast and the contents of the armpit. On histological examination the tumour was found to be a typical cancer of the scirrhous type. She went home in three weeks quite well.

On August 19th, 1908, she was readmitted, having enjoyed perfect health from the date of her last residence in hospital until about six months ago—that is, for eleven and a half years. At that time she began to experience much constipation and also began to be troubled with frequent small stools containing blood and mucus, and appeared to be losing flesh. Digital examination of the rectum showed a hard prominent mass ringing from the right side and ulcerated on its surface. The tumour was not markedly fixed and was situated at about the level of the cul-de-sac of the vagina. In my absence on holiday, Dr. George H. Edington, one of the assistant-surgeons of the hospital, excised the tumour, uniting by suture the cut and apparently healthy ends of the bowel. Microscopic examination showed that the growth was an adenocarcinoma.

No one will doubt that this attack of cancer was an independent development, considering the irrelevancy of the rectum to the mamma, as regards the question of secondary infection. The determination of whether a

*Delivered under the auspices of the North of England Glasgow University Club.

late recurrence of mammary cancer after operative removal is to be regarded as directly connected with the first manifestation of the disease, or not is a much more difficult matter when the site of the recurrence is in so closely co-related an organ, in this respect, as the other breast.

CASE III.

In January, 1896, I was asked to see Mrs. D., a lady then about 50 years of age and of very stout habit of body, with a tumour of the right breast, which there was no difficulty in recognizing as a carcinoma. There was evident but limited cancerous infection of the lower glands of the axilla. Examination revealed no sign of the disease elsewhere. She had been conscious of the presence of this lump in her breast for at least a year. On January 29th, 1896, I removed the breast and axillary contents. Microscopic examination showed that the tumour was a scirrhus cancer, and that the disease had already reached some of the lower axillary glands.

She remained perfectly well for ten years and eight months, when she discovered a precisely similar lump in the remaining breast. This I saw with Dr. Roxburgh of Pollokshields on October 9th, 1906, shortly after its discovery by the patient. On October 16th I removed the breast and axillary contents.

I saw this lady recently (December 24th, 1908). I found her in perfect health, and could not detect, on either side of the body, any indication of recurrence.

Such a case as this I am inclined to regard as an example of a second invasion of the disease. I am well aware—too well aware—how very often, and sometimes how very soon, the second breast becomes infected from the first by way of the lymphatics, but almost always with evidence of recurrence in other situations—in skin, subcutaneous space, bone or cervical glands. But here we had the disease appear in the second breast, there having been an absolute immunity of more than ten years after the operation on the first breast. From that date it is now more than thirteen years, and the lady still continues in perfect health, and with no sign of cancer in any part of the body. In these two women cancerous disease appeared on a second occasion of their lives, but in both of them in a part of the body which is a most usual and well-known site of its primary manifestation—namely, in the rectum and breast respectively. It is quite otherwise in the case of Mrs. E., to whom I first referred; and the fact that the tumour grew under the pectoral muscle is quite fatal to the supposition that it originated there, or, in other words, that it was a primary growth. It must therefore have been a residue, probably in some lymphatic vessel traversing the subpectoral fascia. There it lay for seven and twenty years, obsolete and inactive, but not incapable of recrudescence and rapid growth under conditions and circumstances of which we have no knowledge. We neither understand its long sleep nor its awakening. But I shall narrate another case which illustrates the same power of dormancy and revival in a microscopic piece of cancerous epithelium or some germ of cancer in a situation in which the occurrence of primary cancer would be, if I may be permitted so to express it, still more impossible.

CASE IV.

In 1894 I removed the left breast of Mrs. F., aged 40, a patient of Dr. Anderson of Gt. Glasgow, on account of scirrhus cancer. This diagnosis was verified by microscopic examination. She was a farmer's wife, and remained in excellent health until 1903, performing all the duties of her household and of a large dairy. Early in that year she began to complain of rheumatic pain in the left hip and thigh. This became so disabling that she was compelled to take to bed in March and put herself under the care of her doctor. On getting out of bed one day the left femur fractured. She died four months afterwards.

At the time when the fracture occurred Dr. Anderson wrote to me as follows:

"I can discover no trace of cancer in the breast or elsewhere. The situation of the operation wound is marked by a soft and beautiful scar, and there is nothing in the way of disturbance of function anywhere to point suspicion."

Dr. Anderson has since further informed me that she died from gradual exhaustion, and that there never was any evidence which he could discover of further dissemination to lungs, liver, or bone, nor were there any nodules on the surface of the body.

In this case some fragment or germ of cancer—whether carried, as Handley believes, by lymphatic permeation or by the blood stream does not matter—obviously resided for nine years or thereby in the marrow of the femur and made no sign. Then, waking up to activity, it increased, until by quick growth it gave rise to pressure, to destruction of the bone, and to spontaneous fracture. Unfortunately, neither in this case nor in that of Mrs. E. was there any

post-mortem examination; but so far as clinical signs were concerned there was no evidence elsewhere of the disease.

A consideration of facts such as these leads us to recognize how unwise it is to regard patients who have been operated on for mammary cancer as permanently cured because they remain free of any indication of recurrence of the disease for three, four, or five years. Nor has the remote uncertainty of result, even when for many years the patient has remained in excellent health, been entirely removed by the more extensive operations which have obtained since, for instance, Mrs. E. was operated on. She had the breast, with some of its overlying skin, alone removed. Not even the axilla was interfered with, and yet she remained perfectly well for twenty-seven years. We are apt to forget that good results used to be occasionally obtained even by such a limited operative procedure, and the younger surgeons of to-day seem to believe that by no other than a very extensive operation is it ever possible to prevent an early recurrence. But I well remember, when a student of the old college in the High Street of Glasgow in the early Sixties, that Mr. Lister, no doubt keeping in view the experience of Mr. Syme, used to teach us that if the entire breast with the nipple and such overlying skin as seemed necessary were removed, freedom from the disease might, in certain cases, be long enjoyed and the patient live, perhaps, until some other disease put an end to life. Most other teachers were at that time, on the other hand, fond of declaring that every case of removal of the breast was necessarily followed by comparatively early recurrence and death, and they tried to dissuade patients from submitting to operation. In this connexion I was interested to read, in the *BRITISH MEDICAL JOURNAL* of April 15th, 1905, a letter by Dr. A. W. George, headed *Death from Cancer Twenty-two Years after Primary Operation*. The letter was as follows:

I have recently lost a patient whose case is, I think, worth placing on record. She was a maiden lady, one of a large family, in which a strong tendency to cancer seemed to exist. An elder sister, also unmarried, died from cancer of the uterus, while a younger sister, also single, died of this disease, primarily, of the stomach. At the age of 50 my patient had the right mamma removed by the late Mr. Durham; the axilla was untouched, and for seventeen years there was no recurrence. Five years ago a small nodule was discovered just below the scar; this was removed, and a microscopic examination showed it to be a true scirrhus cancer; a little more than a year later another nodule was removed. About the same time the inner end of the scar became gradually fixed to the chest wall by a deep growth too firmly fixed for removal; this slowly increased till it threatened to ulcerate. Somewhat later Roentgen rays were tried, and, for a time, seemed to check the rapidity of growth. Finally the skin ulcerated, the tumour sloughed, leaving a large malignant ulcer, which spread with a threatening of hæmorrhage occasionally, the patient emaciating and succumbing to exhaustion at the age of 72. At no time was there any sign or symptom of a secondary new growth, nor was it even necessary to administer sedatives, as the disease was painless throughout.

Here, then, are at least two instances of patients surviving for prolonged periods after cancer of the breast was removed without even the axilla being touched—Dr. George's patient for twenty-two, and Mrs. E., whose case I have detailed, for thirty-three years. I accentuate this fact not to deprecate more extensive procedures—very far from it—but merely to offer a contradiction to the belief that no good result is possible without them. Like all other surgeons, I have now for a great number of years in every case cleared out the entire contents of the armpit and removed the breast, with more or less of overlying skin, in one continuous mass. These complete operations have undoubtedly increased the number of our so-called "cures"; and it may be hoped that the still more extensive operation of removing also the pectoral muscles, and perhaps the upper part of the anterior layer of the rectus sheath too, as recommended by Mr. Handley, with the view of preventing epigastric invasion, may result in even more gratifying progress. My own experience and, I should think, all other experience is still too recent to admit of any positive conclusion in this respect. But I have been long satisfied that whether we operate, as we think, early, or whether we operate obviously late in the disease, whether by limited or extensive removals, we must remain uncertain of our results. If we escape early we may still have late recurrence. Our patients may live for

many years and die of some other ailment, and these are the only cases to which we are entitled to apply the word "cure," unless, indeed, we may safely do so to those who live for more than thirty years after operation and remain well. I was much interested to read in the *Epitome of Current Literature in the BRITISH MEDICAL JOURNAL*, October 5th, 1907, similar views quoted from a paper by Bircher in the *Zentralblatt f. Chirurgie*, No. 26, 1907. He there states that the hopes that by modern methods a permanent cure of malignant disease might be effected have been realized only to a slight extent. Instances have been recorded of cases remaining well for ten, twenty, or even more years, but even in cases of this kind there can be no certainty. Statistics prove that retarded relapses occur, in spite of Volkmann's assurance of definite cure after freedom from recurrence for three years. They occur most frequently in the first decennial period after operation—more rarely in the second—and in the third they have been very seldom observed. Hirsch has reported a case in which the patient remained free from recurrence during twenty-five years; while Boeckel and Vernetil each records a case of like freedom during a period respectively of twenty-nine and thirty years. Bircher himself details an interesting case in which the disease appeared again in the scar twelve years and eight months after operation. This was removed, but five months later death took place from metastasis in the liver. He raises the question whether such an experience is an example of real recurrence or of fresh disease, and is of the opinion that such an attack cannot be explained by the view of a local disposition to cancerous disease, as the sudden outbreak of local recurrence and of metastasis must have been due to the influence of some factor favouring the proliferation of latent germs.

But if the character of the operation performed in respect of its extent is not always the explanation of a subsequent prolonged freedom from recurrence, the statement that early operation will ensure success is equally fallacious, and that for a good reason—namely, because it is impossible to know when we operate early and when we do not. Every modern surgeon operates as soon as possible after he has been consulted, and we all desire that patients should consult us at once, when they have found the slightest hardness or tumour in the breast. But clinical experience teaches clearly that the small size of a growth and its recent discovery by the patient do not necessarily mean that it is of recent origin. Nay, more, some cancers of the mamma shed themselves freely into the lymphatic system while still too small to be discovered even by the expert touch of the skilled surgeon, while not very seldom growths of considerable size, and which have been known to the patient for months, have not yet been disseminated as far as the axillary glands, as may be proved when these glands are afterwards removed and histologically examined. In this, as in so many other clinical respects, different examples of the disease constantly contradict one another.

CASE V.

Some years ago I was consulted by a lady from whose armpit a tumour had been removed by another surgeon nearly a year before. I was told it had been found on examination to be of a cancerous character. She was sent to me on account of a small hard tumour of the corresponding breast, which she had recently discovered. She was quite clear that at the date of the former operation nothing of the sort existed or, at least, could be felt. On removing the breast and the contents of the armpit, examination proved that carcinoma existed in both. What the ultimate result was as regards recurrence or otherwise I do not know, as I early lost sight of the patient.

CASE VI.

In the autumn of 1904 an elderly lady, who was then on a prolonged visit to Scotland, consulted me on account of symptoms due to a pretty extensive local recurrence of cancer after removal of the left mamma. The history of her case was as follows: Towards the end of 1901 a tumour of the lowest part of the armpit was removed by a distinguished London surgeon. It had been in existence for a few months. The surgeon made a careful examination of the mamma, but found nothing amiss with it, and contented himself with the removal of the recognizable disease. In October, 1903, a friend of mine in the south of England, who is a well-known and experienced operator, removed a recurrence from the neighbourhood of the scar. The patient soon returned with a second recurrence, and he advised removal not only of that but also of the breast, although on neither occasion did a careful search detect any tumour in it. To this, however, she would not then consent, and, perforce, he contented himself with the removal of the recurrent nodule of

cancer. On March 17th, 1904, however, on her once more seeking his aid on account of return of the disease near its old site, he removed the breast and cleared out the axilla. A small tumour was contained in the breast. I saw her in the autumn of the same year, when there were present great oedema of the limb, scintillating subcutaneous and cutaneous nodules in and around the scars, with hard masses in the infraclavicular and supraclavicular regions. The particulars I have given of her case were communicated to me by my friend, who had recommended her to consult me, distance preventing her from having recourse to himself. In a correspondence which subsequently passed between us, he wrote, "I cannot explain the condition in the old lady; but there remains the fact that neither I nor I, later on, could feel any evident disease in the breast till recently I removed it."

CASE VII.

Quite lately (November 13th, 1908) a patient was admitted to my female ward in the Glasgow Western Infirmary, whose case illustrates the same clinical precedence in the observation of the secondary axillary cancer before the primary mammary tumour is large enough to be demonstrable. She was a woman of 56 years of age. About a year previously she noticed a swelling in the right armpit. She thought it was a "gathering," and some time afterwards the skin over it became discoloured and ultimately burst. It discharged no "matter," but bled very freely. Neither she nor her doctor discovered anything wrong with the breast. But about two months after this she observed a small but very hard "swelling" in the breast. It had since grown larger and become the seat of occasional shooting pain. On examination I found a very large, hard and fixed mass in the axilla, which had invaded the overlying skin, giving it a crumpled and puckered appearance. Three of these puckers or long creases in the skin ended in an ulcer attached to the glandular mass and covered with a dry scab. The tumour of the breast was very much smaller than that of the armpit. The supraclavicular glands also constituted a hard tumour.

These and other cases have convinced me that a mammary cancer may produce extensive involvement of the lymphatics even before it is of a size which renders it demonstrable. *A fortiori*, a tumour which is very small and has only recently attracted the patient's attention and caused her to seek advice must not be regarded as necessarily a very favourable one for operation. An early metastasis or local recurrence often follows operation in such a case, as I know by repeated experience, whereas sometimes a relatively large mammary tumour, whose existence may have been known to the patient for at least a year, may be followed after operation by a long immunity from recurrence, as in the case of Mrs. D. which I have narrated. This is only another instance of the contradictions which one observes in the clinical facts of different instances of the disease.

I was interested to find lately that another surgeon has been drawing attention to this same fact. In the *Transactions of the American Surgical Association*, vol. xxv, page 78, Halsted of Baltimore writes:

I have twice seen extensive carcinomatous involvement of the axilla due to mammary cancer, which later in neither instance became palpable or demonstrable for a considerable period after the axillary glands had attained conspicuous dimensions. In each case the axillary tumour had been removed, in one of them a year before and, in the other, perhaps two years prior to my first examination, which, though made in the most careful manner, failed to find the slightest evidence of cancer of either breast. In the course of a few months thereafter the mammary disease manifested itself in both patients.

Facts such as these prove that, in tumours of this character, small size and recent origin are by no means convertible terms. The little secondary cancerous tumour which I removed from the subpectoral space in the case of Mrs. E. was not bigger than the last phalanx of a little finger, and yet we know that twenty-seven years had passed before it attained to that size. How long a small primary tumour may have been in the making or how soon it may begin to disseminate itself, it is impossible for us to know. Every surgeon ought, therefore, to operate as soon after the discovery of a mammary tumour as he can, removing the whole contents of the armpit, and, if there be no serious reason to the contrary, one or both pectoral muscles as well. But it is equally his duty to remove the entire mamma when operating upon an axillary tumour which appears to be cancerous, or is subsequently proved to be cancerous by histological examination, even though he can discover no tumour in the breast.

I have narrated an instance of cancer of both breasts (Mrs. D.), the disease in the second occurring more than ten years after the removal of the first. The patient still continues well, two years and four months having passed since the second operation. I have expressed the hope, if not the definite opinion, that this is an example of a

primary tumour forming in the left breast, just as happened more than ten years previously in the right one. On one other occasion only have I met with any experience at all similar, and in that case the interval between the occurrence of the disease in the two breasts was a somewhat shorter one—namely, six years.

In all other cases in which I have seen both breasts affected, the appearance of the disease in the second breast has been only an episode in its progressive and continuous advance, even when that advance has been sometimes very slow. If no other evidences of dissemination are yet apparent, they immediately become so. Although I have in several cases removed the second breast under these circumstances, the procedure has always been followed by disappointment. The infection of the remaining breast, like that of the cervical glands, indicates a degree of generalized infection which seems to me to render further operative interference unnecessary and undesirable. And one is the more inclined to pursue this policy from the knowledge that a secondary dissemination of cancer in a breast is usually slower in growth and less likely to give rise to pain, ulceration, and other troubles than a primary tumour in the same situation. I shall shortly describe the disease as it occurred in two sisters, patients of Dr. Sloan of Catrine, since both cases illustrate several important points, and amongst others the secondary infection of the remaining breast.

CASES VIII AND IX.

In November, 1894, I excised the left breast of Miss I. S., aged 55, and cleared out the armpit. In January, 1896, I operated for recurrences in the neighbourhood of the scar; and again in October, 1898, and November, 1899. On November 7th, 1900, I removed the right breast and the contents of the right axilla, on account of disease in those parts. On April 3rd, 1901, another small nodule was found near the scar on the left side and cut out. On August 10th, 1901, I have it noted that the patient called to report herself, and on careful examination I could detect no sign of disease, locally or generally. Fourteen months afterwards, however, she developed signs of disease in the lumbar spine and elsewhere, suffered much pain, lost flesh and strength quickly, and died in January, 1903, thus surviving the first operation eight years and two months.

Her sister, Miss A. S., aged 62, was operated on (left breast) in May, 1904. Within a month or six weeks this was followed by a copious crop of cutaneous and subcutaneous nodules, then by disease of the remaining breast and a metastatic tumour of the liver, with deep jaundice. She survived the operation not much more than a year.

Here were two sisters, very like each other in personal appearance, affected in the later part of their unmarried lives with cancerous tumours of very similar character, so far as physical signs and microscopic examination showed, treated by the same operation, performed by the same surgeon, but with widely differing results. In both the disease proved fatal. In one it took more than eight years to accomplish the patient's destruction; in the other life was at an end in sixteen months.

In the first of these two cases we may believe—at all events it is pleasant to believe—that operation prolonged life; in the other, as all of us must have had occasion to feel in regard to such cases, it probably shortened it.

Up to the date of my operating upon the second sister, her tumour, the existence of which had been known to her for six months or so, made comparatively slow progress. Within a few weeks of my operating on it, there was a destructive dispersion of cancer with a rapidly fatal issue. I have too often in my life had the same sort of experience, and one cannot help, on such occasions, entertaining the feeling that the mere mechanical interference with the disease has caused its immediate and wide diffusion, and precipitated its fatal issue.

This sort of experience seems to bear a close analogy to what follows every now and again after operations undertaken for surgical tuberculous disease. It is one of several resemblances which clinically may be observed between the behaviour of mammary cancer and that of various forms of surgical infective disease. The violent stimulus and injury which is inflicted, for instance, upon a tuberculous ailment, whether of bone or of the soft parts, when it is operated upon, has been found pretty often to be quickly followed by dissemination of the tubercle to the lungs or the cerebral meninges, or even by a generalized miliary tuberculosis. Verneuil¹ and others have collected and published very many illustrations of this fact; and of such experiences I, like others, have had my share. Thus, upon the only occasion on which I ever ventured to apply

the sharp spoon, and that with much gentleness, to the interior of a tuberculous kidney, after evacuating a large abscess by lumbar incision, the procedure was followed, after a few days of relief and quiet, by violent headache, high fever, vomiting, squinting, convulsion, and coma. Death occurred ten days or so after the operation from tuberculous meningitis. The patient was a nurse 35 years of age. I have seen the same mishap follow castration in a patient suffering from tuberculosis of a testicle. The disturbance of tuberculous joints, whether undertaken for diagnostic purposes or with a view to rectifying displacements, constitutes a real danger in this respect. A good many years ago I saw, on more than one occasion, with Dr. Barr Pollock, a boy of about 12 years of age, who suffered from hip-joint disease. He had been kept at rest by means of the long splint, with weight and pulley, for more than two years, and was making excellent progress. Another surgeon, who was consulted at this time, moved the joint freely under an anaesthetic for purposes of better diagnosis, giving his opinion afterwards against any operative interference, and recommending a continuance of the treatment hitherto used. Within a week the boy developed the signs of a meningitis, of which he died in less than a month. I once had a girl of 18 or 19 years of age under my care with a caries of part of the tarsus which had existed without dissemination or serious effect on the general health for eleven years. I scraped it with the sharp spoon, and this was soon followed by tuberculosis of the sternum and the apex of one lung.

I might easily adduce other examples of this form of surgical calamity, but I mention these with a view of attracting your attention to the resemblance they bear to those distressing and quick explosions of cancerous recurrence which now and then follow the removal of the mamma. The clinical fact is enough to make us, as far as possible, avoid all undue pressure upon and squeezing of the tumour, whether during diagnostic manipulation or during the operation for its removal.

The other sister whose case I have referred to lived for more than eight years after operation, although she suffered throughout from the disease. The reason of this clearly was that, whereas in the rapidly fatal case an early metastasis to the liver occurred and precipitated death, in her sister the disease remained external throughout.

Here again we have a striking resemblance to the behaviour of certain cases of infective diseases. It would seem *a priori* almost incredible that a young child should develop in a few months dozens of tuberculous lesions on the surface of the body, thus proving the free circulation and movement of the tubercle bacillus, and yet escape all infection of peritoneum, meninges, pleura, lungs, kidneys, or other internal organs to which childhood is so very prone. And yet such an occurrence is almost a matter of everyday experience.

I lately treated, along with my friend Dr. Ferguson of Paisley, a child, whose case is a striking, but by no means rare, example of that to which I refer. Its only unusual feature, perhaps, is that the patient was the child of wealthy parents, such cases being most often seen amongst the poor. She was born in May, 1900, and was a singularly plump and beautiful baby. In February, 1901, a livid nodule formed in the skin of the left cheek. This, ultimately softened and was scraped, the resulting sore being about the size of a shilling. In May, 1901, two similar nodules appeared in the same cheek, and one in the right cheek. When she was 15 months old the edge of the malar bone near the outer corner of the left orbit became infected and gave rise to an abscess. Two months later a similar lesion declared itself on a similar spot on the other side of the face. Small sequestra ultimately separated from these situations. A month after this an abscess connected with the lower maxilla declared itself and was opened. Ultimately a considerable sequestrum separated. By June, 1902, she had developed fourteen other lesions—in metacarpus, proximal phalanges of the fingers, metatarsus, proximal phalanx of one great toe, and also in cervical glands. Many small subcutaneous cold abscesses formed after December, 1901, and one of considerable size showed itself in the left loin. This was treated, with most satisfactory results, by emptying it and injecting iodoform emulsion in glycerine. Most of the lesions of bone and the soft parts were treated with the sharp spoon, while sequestra were removed when loose, and one or two cervical glands were excised, in operations performed from time to time. The last of these was performed in June, 1903. In the beginning of 1904 every lesion was healed. During her long illness the child emaciated and looked ill, being fretful and peevish. The lesions in the external parts of the body numbered twenty-eight

in all. Never once, however, did she exhibit the slightest sign of disease in abdomen, chest, or head. Now she is a vigorous, healthy-looking child, nearly nine years of age, full of life and spirit, and not so much disfigured as might have been expected.

I can well remember cases of pyaemia in the Glasgow Royal Infirmary, in the dark days of surgery more than forty years ago, in which multiple abscesses, in the same way, remained confined entirely to the external parts, and in such cases—and they were the happy few—recovery often occurred. The surgeons of that day were not unfamiliar with them, and they were referred to as cases of "external pyaemia." In his *Illustrations of Clinical Surgery*, vol. i, p. 229, Sir Jonathan Hutchinson, referring to this matter, remarks:

It may be that the term "external pyaemia" is founded only on a few coincidences, but there is no doubt that amongst surgeons the opinion prevails that when with pyaemic symptoms abscesses develop in the cellular tissue, the case has about it an additional amount of hope.

Of course no case of disseminated mammary cancer, even when the lesions continue entirely external, can be expected to undergo cure, as may often happen with tubercle and pyaemia; but some of them live for a long period of years—some have been recorded who survived for twenty years—and in the case of others even disappearance and cure of individual cancerous lesions, quite apart from any treatment, have been observed. Of this fact of long survival, when for some inexplicable reason dissemination does not reach internal organs, I could adduce a good many examples. I shall mention only two.

CASE X.

One pursued its course from first to last uninterrupted by any operation. This was the case of a lady whom I saw many years ago with the late Dr. Paterson of Bridge of Allan. Several of her near relatives had been operated on for the same disease, and in all of them somewhat early recurrence and death had taken place. She therefore stoutly refused the suggestion of operation. I saw her again about thirteen years afterwards in her house in Glasgow, with her medical attendant, on account of a very severe haemorrhage from a spot in a large cancerous ulcer, which occupied the situation of the breast. All over that side of the chest there were scattered nodules of cancer. The upper limb on the affected side was greatly distended with oedema, and masses of cancer were obvious in the axilla and above the clavicle. Yet, though wasted and cachectic in appearance, this lady had not been confined to bed, did not suffer great pain, and in many ways had continued to enjoy her life. She did not die for some considerable time after my visit, being well over 70 years of age at the time of her death. She never resorted to the habitual use of any form of opiate.

The following case illustrates quite as strikingly the external character of the disease and the consequent comparatively long duration of life.

CASE XI.

In December, 1901, I was consulted regarding the case of Miss D., a patient of Dr. Arthur Mechan. She was then about 40 years of age, and, I was informed, had been operated on in 1898, two and a half years previously, on account of carcinoma of the breast; and now some nodules of the disease had appeared in the scar. These I excised, and repeated the procedure six months afterwards on account of a fresh crop of recurrent nodules. Before long others began to appear in and around the scar, while there were hard cancerous glands at the root of the neck and unmistakable signs of the disease in a dorsal vertebra, with slight angular curvature and pretty severe pain encircling the chest. Nevertheless, she continued going about till about a year ago, and appeared to enjoy life in spite of her disease, which continued to progress. By aid of the constant use of morphine, she accomplished the daily necessary household shopping, made calls on her friends, occasionally went out to dinner, and often attended concerts. At Christmas, 1907, she was present at a tea party given one afternoon, in my female ward in the Western Infirmary, by some ladies, to the patients, and evidently enjoyed the novel experience; but for a year past she had been much weaker. Later, when she was getting out of bed one day, one femur broke. Her weakness then quickly increased, and she sank and died, having survived the amputation of her breast about eleven years. At no time was there any indication of disease in thorax or abdomen.

Mr. Herbert Snow has remarked that "the 'favourable conditions' for long life in cancerous patients mean the induction of the most passive and vegetable existence that it is possible to secure, the aim being to procure and to sustain in such the utmost tranquillity of body and mind," and advises the free use of morphine. It is worthy of remark that this lady took morphine very freely throughout her long illness, using latterly as much as $1\frac{1}{2}$ grains of that drug by hypodermic injection every twenty-four hours.

The late recrudescence of the disease in a patient who has, for many years, survived an operation for cancer of the breast, and in regard to whom our anxiety has long ago been lulled to rest, instances of which I have already cited, may be regarded as illustrating another analogy or resemblance between the behaviour of certain cases of cancerous and of some other infective diseases. Paget drew attention, in a well-known essay, to the frequency with which lesions of tuberculous disease and of osteomyelitis, long ago healed, are apt to relapse and once more waken into activity. This essay was entitled *Residual Abscess*, and in it he wrote of inflammations and abscesses occurring in connexion with the residues of former attacks of disease. "Under the name 'residual abscess' I would include," he wrote, "all abscesses found in and about the residues of former inflammations. Most of them are found where pus, produced long previously, has been wholly or in part retained and become dry or in some form 'obsolete.' But some of them, it is probable, are formed in the thickenings, adhesions, or other lowly-formed products of inflammation long past."² This essay was written in pre-bacteriological days; and, in the light of more recent knowledge, the clinical fact must be explained rather by the reawakened activity of latent germs in the part than by any influence of the residual products of the former inflammations which, by their action, those germs originally furnished. Every surgeon has had cause to observe cases of relapse in after-life both of tuberculosis and osteomyelitis, the primary manifestations of which may have taken place in early infancy.

I conversed only a few weeks ago with a gentleman now in his 69th year, who suffered from hip-joint disease when 5 years of age. He was ill and confined to bed for many years, and all his boyhood was passed in great pain. His hip became dislocated and since continued to discharge till he was about 15 years of age. From that time, however, he continued fairly well, attending school and afterwards entering upon a business life. At 31 years of age he was laid up for a considerable time, an abscess forming and bursting at the old cicatrix. In six months it had healed. He remained in good health and actively engaged in business until he was 52, when he came under my care with a large abscess of the hip, which did not permanently close for more than three years. Once more, since then, he has enjoyed excellent health.

The same tendency to recrudescence is observed in staphylococcal infection of bone years after what seems a satisfactory and absolute cure.

A well-known citizen of Glasgow recently died, being over 60 years of age, who passed through a prolonged and dangerous illness under my care when he was about 20. When 7 years of age he suffered from osteomyelitis, with extensive necrosis of one femur, but, after a long illness, recovered. When I attended him he had great pain, swelling, and tenderness in the same part, with very high fever and delirium. Ultimately I evacuated an abscess which contained nearly a pint of pus. After recovery he once more led a strenuous life, building up an important and very extensive business. In addition, he was a member of Parliament for several years and the author of more than one literary venture. These facts show that he was able to lead an active life. Nevertheless, his old disease again laid him aside on two different occasions for a week or two with recurrent inflammations, without, however, any abscess formation. It had no share in bringing about his death.

Perhaps no more striking example of a recrudescence of latent organisms can be cited than that which is occasionally observed when a periostitis or osteomyelitis has occurred, say of a tibia, during convalescence from an attack of typhoid fever, and has once more subsided. Several years, it may be, after such a bone ailment (cases have been recorded where ten years have elapsed) inflammation may once more occur, and may end in abscess formation. On cultivation the pus is found to yield a pure culture of the typhoid bacillus. I have met with this experience both in connexion with bone and with the gall bladder.

One cannot help recognizing in such occurrences at least a superficial resemblance to those cases of late recurrence of cancer where residual fragments—or may it be resting germs?—of cancer wake up to activity long after apparently assured cure, bring about fresh proliferation and dissemination, and so accomplish the postponed death of the patient.

Our most favourable results, then, if my experience has not been exceptional, are not to be regarded as due necessarily and always to the form and extent of our operation or to the date of our interference relatively to the size of the tumour. They seem due rather to the

essential character of the individual tumour and the degree of invasion of the lymphatic system of the part in each individual case. If the upper axilla be involved as well as the lower, the prognosis is the more doubtful: if there be obvious infection of the skin, especially in the form of detached separate nodules near the seat of the disease, the prospect of long immunity from recurrence is very slight, however large an area of skin be sacrificed, while if the disease is apparent in glands above the clavicle, I always now decline to operate. Still the extent of the operation is, undoubtedly, a certain factor in our results. I have mentioned the fact that long-continued good health and apparently permanent cure sometimes, in former days, followed removal of the breast alone; but the much more frequent experience of such encouraging results after the more extensive procedure of also clearing out the armpit has been very marked indeed. While preparing this paper I have either personally seen, or communicated with the medical attendants of, ten patients who remain quite well after operations performed seven years ago and upwards for mammary cancer, verified after removal by microscopic examination. The list only includes one hospital patient, as such patients, for the most part, quickly disappear from one's view, and I have made no search at all amongst former patients, whether private or hospital. These ten to whom I refer chance to have remained within the area of my own knowledge and observation. The periods of time which have elapsed since operation in these cases are respectively thirteen years, twelve years and four months, eleven years and eight months, ten years and eight months, ten years and six months, nine years and one month, nine years, seven years and ten months, seven years and three months, and seven years. In all of these cases the contents of the axilla were removed, but in none were the pectoral muscles interfered with. I believe it would, at any time, have been impossible for a surgeon of thirty or forty years ago, who removed the mammary gland alone, to have made a statement similar to this. Nowadays there are large numbers of surgeons all over the world whose experience of results is of exactly the same character; and this, no one will dispute, is due to the more extended nature of the operation. Whether or not the routine practice of removing the pectoral muscles will mark a corresponding advance is doubtful; but I think it should be followed, in the absence of anything to contraindicate it, since we must do everything we can to be in advance with our operation of any existing dissemination of the disease; and, in any case, the removal of these muscles makes the clearing out of the axilla much more easy and satisfactory, while their absence is hardly at all disabling as regards the future usefulness of a woman's arm.

A Lecture

ON

THE NATURAL CURE OF CANCER.*

BY

W. SAMPSON HANDLEY, M.S., F.R.C.S.,

HUNTHAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND;
ASSISTANT SURGEON, MIDDLESEX HOSPITAL; AND SURGEON,
BOLINGBROKE HOSPITAL.

ON two previous occasions, when I had the honour of occupying this chair, I presented a view of the mode of dissemination of cancer which I had worked out in the laboratories of the Middlesex Hospital. Under the name of the permeation theory, this view met with wide acceptance. In America it has recently found distinguished advocates in Professor W. S. Halsted, Dr. W. B. Coley, and Professor Rodman, and it has been confirmed in the laboratories where it originated by the work of Dr. Victor Bonney and that of Mr. Cecil Rowntree.

My reasons for mentioning these facts are two in number: First, that, although the permeation theory has met with wide intellectual acceptance, its intensely practical bearing on the surgery of every variety of cancer has

not yet been generally realized. In the second place, much of what I have to say to-day is a corollary of the permeation view of dissemination, and it is necessary to show that I have warrant for assuming its truth.

Since the severance of my official connexion with the Cancer Research Laboratories of the Middlesex Hospital upon my appointment to the surgical staff of the hospital in 1906, my researches have been extended to stomach cancer, with the aid of a grant from the Imperial Cancer Research Fund. On a future occasion I hope to have the privilege of bringing forward my results in regard to gastric carcinoma.

In the literature of carcinoma there are embedded a number of scattered observations, usually referring to single cases, which show that under certain circumstances the disappearance of cancerous masses of macroscopic size may occur spontaneously. In a few cases all clinical evidence of the disease has in this way disappeared, and a natural cure seems to have been brought about.

Occurring in what is usually regarded as the type of a steadily progressive malady pursuing its undeviating course to a fatal event, these facts have appeared strange and anomalous to most of the authors who have recorded them. Their possible significance in respect to the cure of cancer, a significance which it would be difficult to overestimate, has been referred to by Mr. Pearce Gould, who, in a lecture on "Cases Illustrating Repair in Cancer of the Breast," pointed out that "we are justified in speaking of repair in cancer, even in its advanced stages," a conclusion which "justifies—nay, compels—a belief in the possibility of the cure of cancer, and gives us an indication of the direction in which a cure is to be sought."

In this lecture I propose to consider, as fully as time and a difficult and elusive subject will allow, the facts which bear on the natural cure of cancer.

I hope to show that, as I have stated elsewhere, "the progress of a cancer is normally accompanied by retrogressive or curative processes"; that the recorded cases of natural repair in cancer, far from being anomalous and exceptional, merely illustrate more strikingly than usual the natural laws which govern every case of the disease. The order of Nature admits of no real anomalies, and is often best brought to light by the close study of apparent exceptions.

AN UNRECOGNIZED LAW OF CANCEROUS GROWTH.

The unrecognized law of cancerous growth which I wish to establish may be stated as follows:

Every aggregation of carcinoma cells has a definite life-cycle, and, after increasing in size for a varying period and at a varying rate, tends spontaneously to undergo degenerative and fibrotic changes. These changes extend from the centre of the mass centrifugally to its periphery, lead to its shrinkage, and terminate in the replacement of the aggregation of cancer cells by a fibrous scar.

In other words, the natural history of a cancer is one of centrifugal growth followed by centrifugal death. It is obvious that the postulate thus stated cannot be completely proved, if only because at the time death occurs the life-cycle of many—and in some cases of all—of the deposits will be incomplete. The most I can hope to do is to produce a certain amount of positive evidence for my proposition, to meet certain possible objections, and, above all, to show that its acceptance drills into order a ragged regiment of apparently anomalous facts, provides a trenchant weapon of criticism for deciding the value of cancer cures, and offers an explanation of the vogue which almost any cancer remedy may for a brief space attain.

To avoid misconception it will be well at the outset to state that the natural cure in cancer is a local and not a constitutional process, and that as a rule it closely follows up, without overtaking, the centrifugal spread of permeation, and so fails to arrest the march of the disease. It is certain that in some cases its vigour is sufficient to strangle the growth in an early stage, or to reduce it to impotence for a long term of years, but as a rule the natural processes of cure go on contemporaneously with

* The permeation theory is beginning to gain adherents on the Continent. At the Congress of the International Society of Surgery, held at Brussels in September, 1908, Professor A. Doyage, in opening the discussion on breast cancer, said: "Les recherches récentes de Handley et sa théorie de perméation nous ouvrent en ce moment des horizons nouveaux."

the active advance of the disease in other parts of the body further removed from the primary focus.

Apparently Complete Spontaneous Cure.

Velpaen believed that the spontaneous cure of cancer never occurs, and although since his time several cases of the kind have been recorded, the disappearance of a cancer which has clinically reached its full development has never yet been absolutely demonstrated by a complete necropsy with a negative macroscopic and microscopic examination of the tissues for cancer. A few examples may be given.

CASE I.

The best known of these cases is that of Mr. Pearce Gould.² There is no need to repeat its details fully. In 1890 the patient had her left breast removed for a "typical scirrhus," microscopically diagnosed. In 1895 she was emaciated and dyspnoeic, with numerous secondary skin nodules, large axillary and supraventricular glands on both sides, and a cancerous fracture of the neck of the left femur. Between March and November, 1896, the skin nodules shrunk, and were converted into keloid scars, the glands disappeared, the fracture united, and all evidence of growth had disappeared. By 1899 all the scars had become soft and supple, and the general condition had further improved. Unfortunately the patient has not reported herself since about 1906.

CASE II.

Dr. G. Mackay⁴ records the case of a woman of 37, who had her breast removed for a microscopically-diagnosed scirrhus. Recurrence took place a year later, locally in the opposite breast, and extensively in the lymphatic glands. Double hæmorrhagic pleurisy, with dysphagia and severe dyspnoea, next came on. From this point improvement began; the pleuritic effusion was absorbed, and all the secondary growths disappeared. Dates, however, and subsequent history are not given.

CASE III.

A woman, aged 56, now in the cancer wards of the Middlesex Hospital, under the care of Mr. Bland-Sutton, had a portion of the right breast removed for cancer at Chichester in 1894. Operations for recurrence in the breast and axilla were performed in 1896 and in 1903. The nipple still remains, and, indeed, most of the breast appears to be intact. That the disease was not entirely cured by the operation was shown by the development of a brawny arm in 1905, two years after the last operation. No other evidence of cancer remains, and it seems fair to consider this case as much one of natural as of operative cure.

Atrophic Scirrhus.

The apparently complete disappearance of a cancer in the acme of its career of dissemination is one of the rarest events in medicine, but cases are by no means exceptional in which from the beginning the natural processes of cure oppose a stout resistance to the growth. Such appears to be the true nature of cases of atrophic scirrhus. These cases include the best examples of the complete natural cure of cancer. In the most marked form of atrophic scirrhus a puckered scar, to which the skin may become attached, slowly forms in the breast. The whole breast becomes somewhat shrunken and the nipple indrawn, but no definite tumour makes its appearance. The disease in this form is usually painless, and the patient's attention is only attracted by local puckering and adhesion of the skin. Two such cases have recently come under my observation. In such cases the patient may die of some other disease, or, after many years, local ulceration or dissemination may terminate the case. It is not improbable that certain chronic ulcers of the stomach, accompanied by great fibroid thickening, are really extinct carcinomata. For every cancer which reaches its full clinical development, even as an atrophic scirrhus, it may be that a hundred are strangled in the process of birth and while still in the microscopic stage. Cases of typical atrophic scirrhus pass by imperceptible gradations into what is known as "ordinary scirrhus."

I recently had the opportunity of seeing, with Dr. Lockhart Stephens, of Ensworth, a woman 80 years of age, still hale and vigorous, who was operated upon twenty-eight years ago by Dr. Snow for cancer of the breast, and at intervals since for local recurrence. The growth was in the left breast and a considerable portion of the gland still remains. No palpable growth can be felt anywhere. She suffers, however, at intervals from swelling and fullness of the supraclavicular triangles, probably due to difficulties in the circulation of lymph produced by partial obliteration of the lymphatic vessels. She also complains

greatly of pains in the head, and of rheumatic pains elsewhere. It appears certain that the process of permeation is still smouldering along her lymphatic vessels, for at intervals transient nodules appear in the scalp, and the subcutaneous tissues of the forehead are rough and granular to palpation, an indication of the fibrosis of the permeated lymphatics.

Without wishing to detract from the credit which is due to the surgeon, I think this case should be regarded as one of natural rather than of operative cure. More accurately it might be regarded as a kind of stalemate, in which the forces of the cancerous growth and the reparative processes are balanced with the utmost nicety, for the growth does not appear to be completely arrested even yet.

Leaving these cases of clinically more or less complete cure, we may now consider for a moment the records of partial or local cure, as evidenced by the disappearance of macroscopic deposits of cancer.

Subcutaneous Nodules.

The earliest observer of the spontaneous disappearance of skin nodules appears to have been Mr. Howard, the originator of the Middlesex Hospital cancer wards. In his *Notes and Observations*, published in 1792, he says, speaking of a case of bilateral breast cancer:

The tumours commence as small, reddish, slightly-elevated, shot-like indurations of the skin, which enlarge until they attain the size of a pea, when they ulcerate, and afterwards not infrequently heal. The mammae were formerly voluminous, but have dwindled down until they are perfectly flat over the chest.

In 1867 Mr. Charles Moore noted at the Middlesex Hospital that subcutaneous nodules can be destroyed by injecting them with glacial acetic acid, but that some weeks later they may reappear. In recent years the spontaneous disappearance of subcutaneous nodules has been recorded by observers too numerous to mention by name.

Even before the disappearance of skin nodules, and while they form little tumours still definitely raised above the surface, I find that the nodules may consist entirely of fibrous tissue, from which all trace of cancerous epithelium has vanished. This stage of fibrosis doubtless indicates approaching disappearance. Skin nodules frequently ulcerate in the later stages of the disease, and the ulcer may heal, as sometimes happens to an ulcerated primary growth.

Epitheliation of Cancerous Ulcers.

Mr. Pearce Gould in 1900 recorded two cases of partial healing of a cancerous ulcer by the spread of normal epithelium over it. In a third case a large ulcer, due to malignant disease of the right breast, completely healed up. The patient died a month after the process was complete, with deposits in the lungs and liver. It is to be noted that the cicatrization of cancerous ulcers does not seem to delay the fatal event of the case.

Union of Cancerous Fractures.

This is not a very rare, though doubtless an exceptional, event. Several cases occur in the records of the Middlesex Hospital for the last thirty years. In one case fractures of both humeri, of the left clavicle and the left femur, had united, while ununited fractures of three metacarpal bones were present.

The Shrinkage of Spinal Metastases.

Professor Osler⁵ has recorded two cases of spontaneous relief from paraplegia due to the pressure of spinal metastases.

The Shrinkage of Cancerous Lymphatic Glands.

This important question has never yet been fully studied, but there is reason to believe that the successful cancerous invasion of a lymphatic gland is frequently preceded by fruitless attempts at invasion, and that lymphatic glands possess considerable power of destroying cancerous epithelium. I have examined sections of enlarged glands in connexion with a primary growth of the uterus which consisted almost entirely of fibrous tissue. In a case of breast cancer in a late stage I have observed an intermittent enlargement of the axillary glands on the side opposite to the growth. On some

² Note, October, 1908: This patient has since died with internal secondary growths, the probable ultimate fate of most cases of the kind under consideration.

occasions these glands were as large as almonds, while on other intervening occasions they were quite impalpable.

Dr. Bonney has lately studied the precarcinomatous changes which occur in lymphatic glands. He finds that enlargement of the gland precedes the access to it of carcinomatous epithelium. Microscopically the enlarged gland shows abnormally large germinal areas, with a great increase in the number of lymphocytes present. Plasma cells appear in large quantities in the stroma and capsule of the gland. The exact significance of these important observations is at present doubtful.

So far I have brought before you the vestiges of repair in carcinoma as traced in the literature of the subject, but I have produced no evidence to show that this repair is a normal event. This gap in the evidence must now be filled in so far as it is possible to do so.

A.—THE MICROSCOPIC EVIDENCE FOR THE CONSTANCY OF REPAIR IN CARCINOMA.

Perilymphatic Fibrosis.

My investigations on breast cancer have shown that the permeation of a lymphatic is normally followed by a curative process of fibrosis. The cancer cells, which at first fill the lymphatic without distending it, by their continued proliferation finally burst the tube of endothelium within which they are enclosed. Around the split lymphatic some extravasation of blood usually takes place, and a dense aggregation of lymphocytes appears. Soon the lymphocytes are replaced by young fibrous tissue, which forms an adventitious sheath for the cylinder of cancer cells set free from the burst lymphatic. This newly-formed fibrous tissue contracts upon the degenerate cancer cells, and they ultimately entirely disappear. The original lymphatic is now represented by a solid thread of fibrous tissue, and the process of natural cure is locally complete.

Figs. 3 and 4 represent this change diagrammatically. Inside the microscopic growing edge G G G the lymphatic plexus is represented merely by a network of fibrous threads.

Perilymphatic Fibrosis in Stomach Cancer.

In stomach cancer the difficulty of following out the various stages of permeation is enormously increased by the unstable nature of the cancer cells. The cells of a gastric carcinoma exhibit the utmost readiness to undergo complete mucoid degeneration. This difficulty, however, has in the end proved to be an advantage. In breast cancer it was impossible, except by inference, to trace the process of perilymphatic fibrosis beyond the stage in which cancer cells clearly recognizable as such are still present in the new-formed fibrous tissue. In stomach cancer, however, I have succeeded in following up the process beyond the stage of the disappearance of recognizable cancer cells. Fortunately there exists a stain—mucicarmine—which dyes mucin a bright red, while it has little or no affinity for any other tissue or material. The use of this stain promises to be of the greatest possible use in the investigation of gastric cancer. So far I have only used the stain for investigating the spread of stomach cancer in the deep fascial lymphatic plexus of the abdomen, to which the growth often obtains access near the navel. The drawing which I show you represents a section of one of the minute areas of young fibrous tissue, evidently of new formation, present upon the deep fascia near the umbilicus. My belief that this and similar areas represented the complete fibrosis of permeated lymphatics would have remained an unconvincing speculation. But mucicarmine brought out minute points of granular debris, stained a bright red, in the centre of the young fibrous tissue, and guessing was thus replaced by the strongest evidence. For it is certain that none of the normal structures of the deep fascia contain sufficient mucus to give a reaction with mucicarmine.

Thus, although in stomach cancer it has hitherto proved impossible to demonstrate all the stages of permeation in a nicely-graded series, such as I have shown in breast cancer, yet a gap in the evidence has been filled. The latest stage of perilymphatic fibrosis, in which cellular destruction is complete, remains no longer a mere inference, but can be shown actually to occur. The vanished cells of stomach cancer, unlike those of breast cancer, leave for a time a characteristic residue which enables

their former presence to be shown by means of a definite micro-chemical reaction.

In this process of perilymphatic fibrosis there exists, therefore definite and unmistakable instance of the natural cure of cancer by purely local processes which form a normal part of the pathology of the disease.

The destruction of cancerous emboli in the arterioles of the lungs, first demonstrated by M. B. Schmidt, is another instance of the local cure of cancer on a microscopic scale, but time will not allow me to enter into the details of the process.

B.—THE MACROSCOPIC EVIDENCE FOR THE CONSTANCY OF REPAIR IN CARCINOMA.

So far the evidence brought forward to show the constancy of repair in carcinoma has been of a microscopic character. But a recent study of repair on its macroscopic side has driven me to the conclusion that reparative processes are just as active and normal in the primary growth and in its satellite nodules on a macroscopic scale, as on a microscopic scale in the blood and lymph vessels. In the large aggregations of cancer cells the process of repair is later in beginning, and longer in its completion. The patient may die while it is still in its earliest stage, so that in some cases it may be difficult or impossible to demonstrate any sign of it. Its primary cause is a degeneration of the cancer cells, the result of a breakdown in their nutrition.

In carcinomata whose cells possess a high degree of proliferative power, the life of the patient is destroyed while the cancer is still in the early stages of its life-cycle. At the other end of the scale, in carcinomata of low proliferative power, the patient may possibly survive the carcinoma. Between these two extremes all gradations are met with. Expressed in clinical language these gradations are known as:

1. Medullary carcinoma.
2. Scirrhus.
3. Atrophic scirrhus.

Medullary carcinoma is a carcinoma of high proliferative power, occurring in young subjects, whose connective tissues are vigorous and highly cellular. A large mass of growth is rapidly produced, and the patient dies in the early or evolutionary stage of the life-cycle of the carcinoma.

The typical scirrhus is a carcinoma of moderate proliferative power. The patient dies in the involutionary stage of the carcinoma, but before its life-cycle is complete.

Atrophic scirrhus is a carcinoma of low proliferative power, occurring in old people, whose connective tissue is poor in cells. In its perfect form the life-cycle of the carcinoma is completed during the life of the patient.

Ulceration of the Primary Growth.

Almost invariably a primary carcinoma undergoes ulceration in the later stages of the disease. The ulceration begins at the centre of the growth and extends centrifugally into its peripheral portion. These facts are among the very elements of cancer pathology, and perhaps for that very reason no explanation of them has been attempted. From my point of view the constant occurrence of ulceration is of deep significance as showing that the death of the oldest portion of the primary growth is a normal event, and that the duration of any local aggregation of cancer cells is a strictly finite one.

Macroscopic Repair in Cancer a Centrifugal Process.

We have already seen that perilymphatic fibrosis closely follows up the centrifugal spread of permeation—that is to say, it is itself a centrifugal process—starting at the infiltrative margin of the primary growth, and extending in the lymphatic plexuses after the fashion of a ripple. The destruction and repair of large aggregations of cancer cells obeys a similar centrifugal law. Both in the primary growth and in each of its satellite nodules degeneration and repair commence at the centre of the mass and spread to its circumference.

Centrifugal Repair in a Secondary Nodule.

In certain of the secondary nodules of carcinoma no intranodular stroma makes its appearance, and the nodules in consequence only attain a very limited size. Such nodules afford the best material for the study of

repair in secondary deposits. The first indication of repair is that the central cells begin to exhibit degenerative changes. The cell body swells and becomes vacuolated. The nuclei begin to shrivel and lose their power of taking up stains. The whole centre of the nodule may undergo liquefaction. The peripheral cells of the nodule, those which abut directly upon the connective-tissue cells, retain the appearance of full vitality.

The next change is the appearance in the centre of the nodule, among the degenerate cancer cells, of a lymphocytic infiltration, which, however, is not a constant event. Still later, when degeneration has extended to the circumference of the nodule, the lymphocytes give place to a mass of connective-tissue cells, vascularized by new capillaries. Umbilication of the secondary nodule now occurs, owing to the contraction of this central mass of fibrous tissue.

The nodule may continue to spread at its margin, but finally the whole mass of cancer cells, becoming degenerate throughout, is replaced by a fibrous scar in which no cancer cells can be seen.

By the courtesy of Dr. Haaland, of the Imperial Cancer Research Laboratories, I am enabled to show you that similar changes may take place in the secondary deposits of mouse carcinoma. This slide shows a secondary nodule

in the lung of a mouse, with advanced central degeneration, and infiltration of the degenerate portion by lymphocytes.

In the large secondary nodules, which present an intranodular stroma, the processes of repair cannot be so conveniently demonstrated, but they are essentially the same. Central degeneration is followed by fibrosis of the degenerate portion, and the nodule consequently becomes umbilicated like a sucked orange. In old metastases, such as this from the liver of which I show you a photograph, the central portion presents no evidence of cancer, and consists simply of dense fibrous tissue.

Centrifugal Spread of Repair as Affecting Groups of Secondary Nodules.

It has already been shown that the microscopic processes of repair in cancer spread in a regular centrifugal manner away from the point of origin of the primary growth. It might reasonably be suspected that, taking a group of macroscopic nodules, the same centrifugal spread of the process of repair would be noticeable, for the secondary nodules near the primary growth are necessarily older than those further away. Indications of the centrifugal spread of repair, as affecting groups of massive nodules, are not hard to find. For instance, in this photograph, which shows subcutaneous nodules round a breast cancer, the nodules in the immediate neighbourhood of the breast are large, confluent, and ulcerated, while those further away are smaller, and have not yet reached the stage of ulceration. But it is very difficult to obtain convincing evidence of the completion of this centrifugal process of repair in groups of nodules, owing to the anatomical complexity of the lymphatic system.

Conclusive observations can only be secured provided that it is possible to watch the spread of permeation and nodule formation in a lymphatic plexus of extensive area, accessible to observation and lying in a single plane, and provided also that the cancer obtains access to this plexus

at a single definite point from which its centrifugal spread commences.

In rare cases of stomach cancer these exacting conditions are fulfilled. In some cases of gastric carcinoma I find that the growth penetrates the abdominal wall at a point in the middle line just above the umbilicus. At this point permeation extends from the subserous lymphatic plexus to the deep fascial lymphatic plexus, and commences to spread centrifugally in the latter plexus. This invasion is followed by the appearance of a crop of subcutaneous nodules spreading centrifugally from the umbilicus. Such a case was recently under the care of my colleague, Dr. Essex Wynter, and on two occasions, the first a month before death, the second at the necropsy, I made careful drawings to show all the subcutaneous nodules present. I would add that the second drawing was made without any reference to the earlier one. The later drawing shows that the centrifugal spread of permeation in the fascial lymphatic plexus had made considerable progress. But this is not the point to which I would especially draw your attention.

In the earlier drawing (Fig. 1) the region immediately around the umbilicus is thickly sown with nodules. In the later drawing (Fig. 2) not a single nodule can be seen within a considerable distance of the point at which the fascial plexus was invaded. These sketches, therefore, afford a convincing and at present unique proof of the centrifugal spread of macroscopic repair as affecting, not single nodules, but groups of nodules.

Fig. 1.—A chart of the subcutaneous nodules, spreading from a point just above the umbilicus, present in a case of stomach cancer one month before death.

Fig. 2.—A chart showing the same case as at the time of death. The nodules have continued to spread, but they have vanished from the region where they made their first appearance.

CAUSES OF CENTRIFUGAL DEGENERATION IN CARCINOMA.

Why does a carcinoma cell ultimately degenerate and die? The phenomenon cannot be ascribed to the hostility of the phagocytes, for it is one of the most striking features of the histology of cancer that degeneration of its cells

precedes in point of time the access of wandering cells to the area of degeneration. Upon this point my observations have been confirmed by those of Bonney. Nor is the degeneration of the cancer cells due to the development of anticancerous properties in the fluids of the body, as Lomer is inclined to think. Beyond the area of degeneration the cells of the microscopic growing edge will be found actively spreading along the lymphatics and exhibiting a vigorous vitality, which sufficiently shows that no anticancerous bodies are present in the lymph. It would doubtless be true to say that failure of nutrition is the proximate cause of the degeneration which carcinoma exhibits.

We have seen that in any group of carcinoma cells the central cells—those furthest from the base of supply—are always the first to degenerate. But there is something special and peculiar about this failure of nutrition, for, as I have previously shown, immersion in the blood stream—the rich nutritive stock and common food supply of the body—is usually fatal to epithelial cells.

No doubt the excessive pressure produced by the active proliferation of the cancer cells is one cause of impaired vitality in the older deposits, and this pressure is increased by the contraction of the newly-formed cellular stroma in which the older foci of growth are embedded. There is, however, another factor to be taken into account, and one the importance of which I have only recently realized. If you look at this section of a permeated lymphatic, much distended and approaching the point of rupture,

you will see that a single layer of cells at the periphery, although necessarily subject to the same pressure as the more degenerate central cells, still preserves the appearance of vigorous life. The chief point of difference in the environment of the peripheral healthy layer of cells is that they, as contrasted with the central degenerate cells, are in immediate contact with a layer of endothelial connective tissue cells. In this section of a stomach cancer which I show you, the dependence of epithelium for nutrition upon actual contact with connective tissue cells is even more strikingly shown. The cancerous epithelium forms everywhere a single layer lining the distended lymphatics of the permeated subserous lymphatic plexus, and all the central cells have entirely disappeared.

The solution of the problem of centrifugal degeneration in cancer appears to be suggested by the two sections I have just shown you.

The Epithelial Cell an Obligate Parasite upon the Connective Tissue Cell.

Certain of the cells of the body—the leucocytes, for example, and probably the haemal endothelium—are nourished directly from the blood plasma. Others, including most, if not all, of the cells of the connective tissue, are fed by the diluted blood plasma which is known as lymph. But the epithelial cells, in the course of their specialization, would appear to have lost this power of taking up nourishment directly from the body fluids. Epithelium appears to depend for its nourishment upon the products of the connective tissue cell conveyed to it, either by actual contact, or at least by close contiguity. The inability of epithelium to nourish itself from the fluids of the body is not a mere theory. I have shown in previous lectures that immersion in the blood stream is nearly always fatal to cancerous epithelium. Veit's work upon the deportation of chorionic villi shows that the same thing is true for the normal chorionic epithelium. Moreover the chorionic epithelium, although specially designed to hang into the blood stream, exhibits by the imperfect segmentation of its cells and the formation of syncytium, a process analogous to that by which the toxin of the tubercle bacillus leads to the formation of giant cells. And I would here remind you that the so-called syncytium is not, as is so often thought, a structure peculiar to the chorion; it may occur in any carcinoma when its cells come into intimate relation with the blood stream.

It would take too long to marshal the facts of normal histology which support this view that the epithelial cell is an obligate parasite upon the connective tissue cell. The many-layered epithelium of the skin which appears at first sight to contradict it, in reality forms one of the best proofs of its truth. The deeper layers of the skin epithelium are penetrated by a network of branching processes, easily visible in the negro because pigmented, derived from the underlying connective-tissue cells. The superficial layers of the epithelium, from which these nutritive processes are absent, are continually dying and being cast off.

In his recent Hunterian lectures,⁶ my colleague, Professor Bonney, has established the new and very important fact that a local increase in the cellularity of the subepithelial connective tissues, accompanied also by a destruction of the elastic tissue, invariably precedes

the appearance of a carcinoma. This increased cellularity is due to a precedent chronic inflammation. But if the chronic inflammation has progressed farther, and has reached the stage of fibrosis and diminished cellularity, he finds that there is little risk of a carcinoma originating in the fibrosed area. Dr. Bonney interprets the effect and mode of action of these changes as consisting essentially in the removal of various obstacles to the process of infiltration. He says:

The tissue cell proliferation results in a rarefaction of the connective tissue in front of the advancing carcinoma cells, in the course of which mechanically resistant structures such as fibrous tissue and elastic fibres become softened and destroyed.

From my point of view,

the precarcinomatous increased cellularity of the subepithelial connective tissues, which Dr. Bonney has demonstrated, acquires additional significance. If the epithelial cell, normal or cancerous, can live only as a parasite on the connective-tissue cell, an abnormal aggregation of connective tissue cells beneath an area of epithelium will obviously tend to promote epithelial activity, and will provide a body of hosts or caterers who will supply the needs of any epithelial cells which penetrate into the rarefied precarcinomatous connective tissue.

Thus Dr. Bonney's observations would seem to offer strong support to my view of the parasitic nature of epithelium. But newly-formed connective tissue, such as is found in the scar of a wound, and in the stroma of a carcinoma, does not maintain its cellular character indefinitely. It becomes more and more fibroid, until

Figs. 3 and 4 are schematic representations of two stages in the life-history of a carcinoma. The lymphatic plexus, *h h h*, and the microscopic regions of the carcinoma, are represented as highly magnified, while the primary growth and its naked-eye secondary nodules are reduced in size.

Fig. 3.—*A Carcinoma in the Evolutionary Stage.* The active primary growth, *A*, is surrounded by secondary nodules, *B B*, and by smaller and younger secondary nodules, *C C*. The circle *F F F* is an imaginary line, separating the clinically appreciable region of the carcinoma from the outlying microscopic region, in which is found *c c c*, the microscopic growing edge of permeated lymphatics. Beyond *c c c* is the normal lymphatic plexus, *h h h*, while inside *c c c* the vessels of the lymphatic plexus, represented as thin white lines, have been destroyed and converted into fibrous threads.

only a few scattered cells, represented by mere nuclei, can be seen within it. According to Dr. Bonney, senescence of the stroma and degeneration of the cancer cells advance *pari passu*. And this is exactly what would be expected from the nutritional dependence of the epithelial cell upon the connective-tissue cell.

If it be granted that the cancerous epithelial cell depends for its adequate nourishment upon contact with a connective tissue cell, the centrifugal processes of repair in cancer become easy to understand. Considering first any small group of cancer cells, their continued proliferation must necessarily remove the more central cells from contact with the surrounding connective tissue, and must therefore lead to degeneration of the centre of the mass. In the second place, newly-formed connective tissue, such as composes the stroma of a cancer, rapidly and invariably becomes senile; that is to say, its cells disappear and are replaced by fibrous tissue, poor in cells, and therefore ill-adapted to nourish epithelium. Such appear to be the factors on which the natural cure of cancer depends.

It will be objected, and with some force, that certain carcinomata, neither at the time of the patient's death nor before, show any evidence of the centrifugal reparation which follows centrifugal spread.

It is certain, of course, that a carcinoma may cause death while it is yet in the infiltrative stage, and before there is any evidence of permeation; that is to say, the primary growth may be the only focus of growth present in the body. But even in such cases, ulceration, commencing at the centre, and spreading to the circumference of the growth, is a practically constant phenomenon, which testifies to the presence of commencing centrifugal repair. The evidence of centrifugal repair may be incomplete and partial simply because the life-cycle of the carcinoma, which probably varies extremely in length, may be still in one of its earlier stages at the time of the patient's death. At any period in this life-cycle, invasion of one or more of the serous cavities may take place, and may cut short the evolution of the growth by producing rapid visceral dissemination and death.

THE LIFE-CYCLE OF A TYPICAL CARCINOMA.

From the facts which I have laid before you I think it is possible to work out a scheme of the life-history of a typical carcinoma.

Stage I.—The growth is infiltrating the tissue interspaces around its point of origin, but has not yet obtained access to the lymphatic vessels which open out of them.

Stage II.—The growth obtains access to the small lymphatic vessels near its point of origin, and permeation

commences to spread centrifugally from this point. At this stage cancer cells obtain access to the trunk lymphatics, and embolic invasion of the lymphatic glands occurs as a minor and subsidiary process.

Stage III.—The permeative growing edge, spreading centrifugally, is cut off from the massive primary growth by fibrosis of the intervening permeated lymphatics. The symptoms dependent on contraction or puckering (retraction of nipple, flattening and shrinkage of the breast) consequently begin to show themselves, and the carcinoma becomes clinically recognizable.

Stage IV.—The massive primary growth continues to increase in size by infiltration. Around it, in the area of perilymphatic fibrosis, small macroscopic satellite nodules begin to manifest themselves. The permeative growing edge is now reaching such a diameter that the verge of operability may be approached (Fig. 3).

Stage V.—Although the growth continues to spread, centrifugal degeneration of the massive or macroscopic deposits is now beginning. It affects first the oldest portions of the cancer. The primary growth becomes degenerate and fibrotic at its centre, and consequently if the growth is on a surface, ulceration begins. The ulcer spreads centrifugally. The secondary nodules nearest to the primary growth degenerate from their centre outwards, and disappear, while new ones spring up in the outlying area of lymphatic fibrosis left in the track of the still spreading microscopic growing edge.

Stage VI.—The proliferative energy of the massive or macroscopic primary growth is exhausted. It ceases to spread, ulcerates to its margin, and finally heals over, leaving a scar from which cancer cells have disappeared. The secondary nodules have disappeared from the area immediately round it, also leaving scars. The centrifugal spread of the permeative growing edge may conceivably at this stage be arrested, but it usually continues to spread indefinitely, leaving in its track fresh secondary nodules (Fig. 4). This cycle of events may be interrupted at any point after Stage II by invasion of the serous cavities, or in rare cases by successful blood infection, and by consequent rapid visceral dissemination shortly terminating in death.

CANCER THERAPEUTICS: A CRITICISM.

The literature of cancer therapeutics does not contain the record of a single fact which cannot be paralleled among the histories of untreated cases. How, then, is the value of any particular method of treatment to be determined? It is futile to bring forward a few isolated cases in which the shrinkage or disappearance of primary or

FIG. 4.—A Carcinoma in the Involutory Stage. The primary growth, A, and the oldest secondary nodules, B B B, have now become completely fibrotic and inactive, and are represented by puckered scars. Fresh nodules, D D D, and others, E E E, still younger and more remote, have made their appearance in the rear of the microscopic growing edge, G G G, which, continuing to spread, has now attained a very large diameter, and is still advancing into hitherto intact regions of the lymphatic plexus, H H H. Within G G G all the lymphatic vessels have been converted into fibrous threads. Other letters as before.

secondary growths has been observed, for these phenomena, as we have seen, belong to the natural course of the disease. Their occurrence as testimony to the value of a remedy would only be significant when they frequently and immediately followed upon its employment in a number of consecutive cases. But in any case where centrifugal spread has been rapid and regular and accompanied by a crop of secondary deposits, and where upon the application of a remedy no further deposits appear, the remedy may be fairly presumed to have exerted an influence. In this connexion it may be pointed out that cases of stomach cancer, with invasion of the fascial plexus at the umbilicus, and with a crop of skin nodules spreading from this point, afford the conditions for crucial experiment in cancer therapeutics which are absent in almost all other cases. The observer sees the growth, as evidenced by skin nodules, spreading from a definite point in a definite plane. With the patient's consent, local measures, such as x rays, might be applied to one half of the body, while the other half remains untreated as a control. The effect of constitutional measures might be determined by their effect on the observed rate of spread of nodules from the navel—a rate which can be determined from week to week, if not from day to day. More careful observation of these cases would give a precision to the study of the medicinal therapeutics of cancer which is at present conspicuously wanting.

It is not too much to say that a study of the processes of natural cure in cancer absolutely destroys the clinical evidence in favour of trypsin as set forth by Dr. Shaw-Mackenzie, the pioneer and introducer of this treatment. And the same thing is true of all other internal medicaments at present known, as judged by the published evidence, with the single exception of Coley's fluid in the treatment of sarcoma, a remedy which appears to possess distinct value. There would seem also to be no doubt of the effects of x rays in promoting the natural tendency to fibrosis in masses of malignant tissue which are directly accessible to the influence of the rays. But a very thin layer of normal tissue is sufficient to protect cancer cells from the action of the rays.

Fibrosis of the primary growth is often interfered with by the onset of sepsis, which necessarily produces increased local cellularity of the connective tissue. The beneficial effects of curettage and escharotics in advanced uterine cancer, perhaps also the temporary good effects of x rays and high frequency currents, are probably partly due to the antiseptic value of these measures. After their use the process of fibrosis of the primary growth is able to resume its normal course, and great local improvement occurs, without any arrest of the spread of the disease.

SECONDARY EFFECTS OF THE PROCESS OF NATURAL CURE.

One of the most striking facts brought out by my investigations is that the permeative spread of the cancer is followed by an almost coextensive destruction of the lymph-vascular system, and by contraction of the network of fibrous threads which replace the system of lymphatic vessels. The consequences are varied and important. They may be considered under the following three headings:

I.—*Contraction of the Tissues around a Carcinoma.*

The defensive process of perilymphatic fibrosis, and not the destructive processes of permeation and infiltration, is the cause of most of the symptoms by virtue of which an external cancer becomes clinically recognizable. In the case of the mamma, retraction of the nipple, flattening and shrinkage of the breast, adhesion to skin and fascia, all these symptoms are evidences of perilymphatic fibrosis, that is to say, of attempts at natural cure of the disease. Their absence is of no value in any given case as evidence against malignancy.

The tendency of a carcinoma to drag in towards itself a wide area of the surrounding apparently healthy tissues, a tendency which has never received a clear or adequate explanation, is an inevitable sequel of the process of perilymphatic fibrosis. If over a wide area round the growth the normal network of lymphatic vessels is replaced by a network of newly-formed, and, therefore, contractile, fibrous tissue, a general puckering and shrinkage of the affected zone is bound to follow.

II.—*Cancer en Cuirasse.*

The leathery thickening of the skin of the chest which is sometimes seen in breast cancer is not in its earlier stages accompanied by any cancerous infiltration of the integument. I have shown that the thin skin of the female breast may in these cases attain a thickness of 6 mm. before any sign of cancerous infiltration is manifest. The condition is primarily a pachydermia or lymphatic oedema of the skin, due to destruction of the fascial lymphatic plexus, and to consequent lymph-stasis. Only in the later stages is the skin actually invaded by cancer cells.

III.—*The Brawny Arm of Breast Cancer.*

According to Mr. Shield, the brawny arm of breast cancer is due to the pressure of a mass of growth upon the axillary vein. But excision of part of the axillary veins is not, as a rule, followed by swelling of the arm, which, moreover, is frequently seen in cases where no palpable axillary growth is present. My senior colleague, Mr. T. W. Nunn,* has pointed out that the axillary veins may be completely enveloped in a cancerous mass, and yet the arm may not be swollen. He believes that the oedematous arm is due to obstruction of the main lymphatics by growth within them, and, no doubt, this is a part of the truth. But ablation of all the axillary glands, which must involve complete interruption of the trunk lymphatics, is not, as a rule, followed by oedema of the arm, doubtless because a collateral lymphatic circulation is established. Some other factor besides obstruction of the axillary trunk lymphatics is evidently necessary.

The permeation theory of dissemination appears for the first time to explain fully the condition. Perilymphatic fibrosis, the sequel of permeation, destroys the affected lymphatics utterly, leaving only fibrous cords to represent the original vessels. The process is not restricted to the lymphatic trunks, but affects also the smaller lymphatics. As soon as lymphatic fibrosis has extended some little way down the arm the lymphatic connexions of the whole limb are entirely severed, and the lymph can only return partially and imperfectly by percolating through the tissue interspaces. A condition of lymphatic oedema results, which in time produces the brawny arm of breast cancer.

The brawny arm may be found fully developed in cases where no evidence of active cancerous growth remains. It is a pachydermia affecting the arm in consequence of lymphatic fibrosis, and is to be regarded rather as an evidence of the activity of the natural curative processes than as a direct symptom of cancerous growth.

THE OPERATION OF LYMPHANGIOPLASTY.

Pending the achievement of larger results by methods which are yet in their infancy, I am glad to be able to show you a minor instance of the immediate fruition of cancer research. I have been able to devise a simple operation by which, if it is permissible to judge from the strikingly successful result of a single recent case, the brawny arm of breast cancer may in future be prevented or cured with restoration of the usefulness of the limb. The problem to be solved was this: How to provide a new set of lymphatic vessels for a limb in which the normal lymphatics have been destroyed.

Without going into detail I may say that the permanent introduction into the subcutaneous tissues of a number of buried silk threads running from the wrist upwards to terminate in the loose areolar tissue over the scapula appears to have solved the difficulty. In the case where I performed this operation the excess of fluid was rapidly drained away from the arm by capillary attraction, and the oedema subsided in a few days, although the condition was of nearly three years' standing. The pain was completely relieved. The operation is, so far as I know, an entirely novel one, and it appears to deserve a distinctive name, for it is probably applicable in pachydermia of every kind, whether due to the filaria, to cancer, or to septic lymphangitis.

I would suggest for it the name "lymphangioplasty," and I confidently hope that its usefulness will not be restricted to cancer, but that it will remove elephantiasis from the list of incurable diseases.

This operation was the direct outcome of pathological

* The results of a number of other cases have since confirmed this expectation. See *Archives of the Middlesex Hospital*, vol. xii, p. 28.

investigations, which showed that the brawny arm of breast cancer indicates arrest rather than great activity of the cancer process, and is produced by lymphatic obliteration. Its success confirms the pathological conclusions upon which it was based, and shows that the more recent methods of pathological histology are full of unexhausted possibilities.

MEANS OF PROMOTING THE NATURAL CURE OF CANCER.

We have seen that the natural local cure of cancer is brought about by fibrotic processes which cut off the cancerous epithelium from that contact with connective tissue cells which is necessary to maintain its vitality. Superficially, at any rate, this process presents some analogy with the natural cure of tubercle, which also takes place by a process of fibrosis. And certain cases in which I have seen great apparent benefit to cancer patients as the result of a change of residence from town to country, or from a sea voyage, lead me to suggest that the open-air treatment, which has proved so successful in tubercle, may be worthy of trial in the more chronic cases of inoperable cancer. The treatment as applied to tubercle would require modification for cancer; the carcinoma patient, for instance, as contrasted with the tuberculous patient, would probably require less food and more exercise; but there would appear to be no very strong objection to the tentative treatment of cases of inoperable cancer side by side with cases of tubercle in sanatoriums. Under no circumstances whatever should the treatment be recommended as a substitute for operation, if operation is possible.

THE TREATMENT OF CANCER BY THE USE OF POTASSIUM BICHROMATE.

By JAMES FENWICK, L.R.C.P., L.R.C.S. EDIN.,
L.M., L.F.P.S. GLASG.,
ACCRINGTON.

[A PRELIMINARY COMMUNICATION.]

THROUGH the courtesy and indulgence of the Editor of the *BRITISH MEDICAL JOURNAL*, I am permitted to lay before the profession, of which I have the honour to be a member, a number of cases of cancer successfully treated by the use of injections of bichromate of potassium into the substance of the tumour. The dose used is from 7 to 10 minims of

a sublimate solution; in some cases 15 minims are injected. In 1906 I submitted a paper on the treatment of rodent ulcer, which perhaps at that time was not of sufficient importance to claim publicity. Since then, however, about 25 cases of cancer treated by my method, with notes, were presented to the Académie de Médecine, Paris (November 29th, 1908). It is these cases, with notes, I herewith present for the unbiased and charitable criticism of my professional brethren.

CASE I.

L. A. R., aged 47. She had her breast taken off at the Victoria Hospital, Burnley, in August, 1907. In January, 1908,

she consulted me, having first consulted Dr. Jackson of Nelson, who informed her that the cancer had returned. There was a lump about the size of a hen's egg in the line of the cicatrix. I commenced treatment in January, and it was quite well in March, 1908. The result of the treatment is that there has been no further recurrence. She has lost the cancerous cachexia, and is looking quite well and feeling strong. This was a case of secondary scirrhus.

CASE II.

Miss N., of Nelson, aged 42. She came to me on May 21st, 1907, with a lump in the breast. This the Clinical Research Association, London, reported on as follows (May 30th, 1908): "This is evidently a malignant growth of a carcinomatous type. But the specimen is too small to say whence it has originated." She was not well until June, 1908, on account of my having been ill with rheumatic fever, and the treatment having been suspended. The photographs show the case when it began to slough, and when (on November 3rd) it was quite well.

CASE III.

Mrs. B., of Bristol, aged about 54. She came to me in June, 1906, with large growth in breast. The doctor in Bristol advised her to have breast taken off for cancer. On examination I found a large growth which had fastened itself upon the ribs just over the heart. She was under treatment about four months. When the slough came away a large portion of one rib came away also. Dr. Laurent, Professor of Operative Surgery at the University of Brussels, saw this case at my house. His opinion was that there had first been some tuberculous condition preceding the cancerous growth. I had a report from her on October 28th, 1908. She is quite well, with the exception of some peripheral neuritis. Her own doctor in Bristol is of opinion that the general neuritis is due to an exposed intercostal nerve—a nerve exposed by the portion of rib sloughing away. She put on 20 lb. in weight after treatment. She looks well and has lost the cancerous cachexia, which previous to treatment was well marked. Dr. Dymoke and Dr. Reynolds, of Bristol, both say it was a case of cancer.

CASE IV.

Mrs. K., of Blackburn, aged 82. She came to me in 1906 with a large tumour in the posterior triangle of the neck. The Clinical Research Association report, November 3rd, 1906, was: "This specimen is a portion of the integument. Its deep surface is invaded by a new growth, which appears to be an epithelioma. There are no cell nests, but the central cells in the processes have undergone granular degeneration. The lesion is evidently a secondary formation." The photographs (see p. 590) show the growth previous to treatment and the condition afterwards. This patient died about December, 1907, from some intercurrent disease; I think it was bronchitis.

CASE V.

T. S., of Accrington, aged 77. He had a rodent ulcer on right side of nose as large as a franc. He went to Dr. Frankish, who told him it was a cancer, and refused to attempt anything for him. He came to me on November 5th, 1907, and was well in seven weeks. I applied bichromate upon cotton-wool to the place, the cotton-wool remaining *in situ* until the following day. He had four applications. Slough followed, which separated in about three weeks, leaving a clean granulating sore, which healed up in a week.

CASE VI.

Mrs. McL., aged 52. First went to Dr. Reid of Preston, then came to me in February, 1908. The Clinical Research Association report, February 14th, 1908, was: "This piece of tissue is infiltrated by a carcinoma, which is spreading along the lymphatics in the cutis vera. The growth has the usual characters of a scirrhus carcinoma." She was quite well on November 3rd, 1908, as she was also at the last report on November 3rd. Accompanying are photographs (see p. 590).

CASE VII.

Mrs. P., aged 53. She saw Dr. Cran Duthie of Blackburn and Dr. Rawlins of Manchester—a cancer specialist—in May, 1907. Both advised her to have the breast off. She came to me the same month, and was quite well by October 20th, 1907. She

Fig. 1.—Case II. Cancer of breast beginning to slough.

Fig. 2.—Case II. Cancer of breast. After treatment.

had about forty injections of 7-minim doses. She came to the surgery about every other day.

CASE VIII.

Mrs. G., of Blackburn, aged 65. She first consulted Dr. Taylor and Dr. Nutter, who told her she was too old to be operated upon. She came to me on May 9th, 1907, and was under treatment twelve weeks. The cancer was in the breast. The Clinical Research Association reported on May 13th, 1907: "This section of nipple shows at one end (marked with ink-line) a small area of tissue infiltrated with carcinoma. The growth seems to be of the columnar-celled type, such as would originate from duct epithelium." She had about twenty injections. She reported herself on November 3rd, 1908, as being quite well.

Fig. 3.—Case IV. Epithelioma of neck. Before treatment.

CASE IX.

A.P., of Blackburn, aged 42. He first saw Dr. Martin, senior surgeon to Blackburn Infirmary, and was operated upon for a growth in the root of the right ala of the nose. He came to me on November 26th, 1906. The Clinical Research Association reported on December 21st, 1906: "This growth is a carcinoma of the skin of the rodent ulcer type. It consists of branching, epithelial columns, possibly arising from sebaceous glands or hair follicles, and infiltrates the tissues with a characteristic rosetted outline." He had about forty injections, and was attending my surgery for about six months. He still keeps in perfect health.

CASE X.

J. H., of Lytham, aged 48. He first consulted Dr. Millan, of Lytham; then Dr. Sellers, of Preston Infirmary. He was operated upon by the latter at Preston Infirmary in November, 1905. He came to me in April, 1906, the growth having returned in four months. I gave him six injections, and he reports to me (November 3rd, 1908): "I enjoy the best of health, and have felt no effect of my lip since you treated it."

CASE XI.

Mrs. T., of Muswell Hill, aged 49. She came to me on June 9th, 1907, with cancer in the cheek, after having been eighteen months under treatment in London without any good result. The Clinical Research Association report of June 12th, 1907, was: "This specimen is a carcinoma of the skin, belonging to the rodent ulcer type. It consists of branching masses of small epithelial cells, and shows a tendency to cystic change in places from degeneration." In nine weeks she was quite well and returned home. I made nine to twelve injections.

Fig. 5.—Case VI. Scirrhus of breast. Before treatment.

CASE XII.

Mrs. B., of Blackburn, aged 57. In March, 1906, she consulted Dr. Bradley, of Blackburn, who advised her to have a lump cut out of her breast. She came to me and I found a lump as large as an egg. I commenced treatment in March, 1906. She had eighteen injections of bichromate (10 per cent. solution) of about 7 minims each, these being given every other day. A slough followed, which stank very much. In September she was quite well, and has kept well ever since. The later of the accompanying photographs (see p. 591) was taken on November 3rd, 1908.

CASE XIII.

Mr. E., of Harlepoolke, Burnley, aged 23. He had a growth upon the upper lip. He first consulted Dr. Marsden, of Burnley, who for eighteen months treated it in various ways. He declared it to be cancer, and advised him to have it operated upon.

The patient consulted me in July, 1906. I used about six injections. A report from him on November 3rd, 1908, says he is quite well and there has been no return.

CASE XIV.

Mrs. B., of Church, aged about 50. She had a lump as large as a duck's egg in the breast. Two doctors told her it was cancer, and advised her to have the breast taken off at once. Instead of having that done she came to me in January, 1906, and by May was quite cured. I have a photograph showing the

Fig. 4.—Case IV. Epithelioma of neck. After treatment.

tumour in the sloughing condition coming away from the previously unaffected skin, and another showing the result after treatment. In November, 1908, I saw her again, and the condition remained healthy. A soft white scar was left. The glands in the axilla, which had formerly been enlarged, had now resumed their normal condition, and the patient said she had never felt better in her life.

CASE XV.

Mrs. A., of Colne, aged 46. She first went to Dr. Doyle of Colne, who said she would need to have her breast off. She came to me on September 22nd, 1906. She had fifteen injections of about 7 to 10 minims of potassium bichromate of unusual strength. On January 21st, 1907, she was quite well, and has remained so up to date (November 3rd, 1908).

CASE XVI.

Mr. B., of Accrington, aged 61. He first saw Dr. Greenwood of Accrington, who told him he had cancer of the tongue. He came to me about June 15th, 1906. He had six injections, and was quite well on September 15th, 1906. Report on November 3rd, 1908: "Quite well."

CASE XVII.

Mrs. P., of Clayton-le-Moors, aged 44. She first consulted Dr. Clegg, Surgeon to the Victoria Hospital, who told her she had cancer of the breast. She came to me on October 19th, 1906. She attended me about three months and had about forty injections. She was quite well on November 3rd, 1908.

CASE XVIII.

Mrs. B., of Blackburn, aged 46. She was operated upon in March, 1896, for a lump in the breast. The lump reappeared in September, 1907. Dr. Steward of Liverpool and Dr. Walters of Manchester (both specialists in cancer) declared the growth to be cancerous in 1896, and its reappearance in 1907 appears to confirm the diagnosis. She came to me in October, 1907. She had twenty injections, after which the growth sloughed out, and she is now quite well. She was under treatment about six months. Reported to me, November 3rd, 1908, as quite well.

Fig. 6.—Case VI. Scirrhus of breast. After treatment.

CASE XIX.

Mrs. D., of Blackburn, aged 47. She saw Dr. Bowen and Dr. Shaw of Blackburn, who said she had cancer of the breast. She came to me in June, 1906, and was under treatment until November 20th, 1906. She had twenty-six injections, after which the growth sloughed out. The report to hand, November 3rd, 1908, says she keeps quite well.

I should like to call attention to two of the cases—namely, Nos. I and X—which prove to my mind that the treatment is superior to operation. Then, again, let me point out the important fact that in Case VII the result of the treatment is that, after the menses had been stopped

for some years, they were re-established, appearing regularly for five days every month without pain, just as in her early and healthy days.

Here, then, as the above cases abundantly show, is a treatment which can be carried out in every surgery. It is simple and inexpensive, within the means of the humblest patient, and I can conscientiously say in respect of rodent ulcer and epithelioma, which I have been treating for fourteen years, that it is a treatment that will be lasting in its effects, if carried out in the manner I will indicate in a future paper if permitted. There need never again be seen a case of rodent ulcer which has eaten away the eye or the frontal bones and exposed the brain. If any such case is seen again it will be the fault of the profession or the wilful neglect of the patient. If called upon for further or more detailed proof I will supply it with alacrity.

Cases Treated by Dr. Pilkington, of Philadelphia.

For the following three cases I am indebted to Dr. Pilkington, of Philadelphia, who came from America to my house in 1906, and stayed for a week in order to learn the treatment:

CASE I.

Geo. F., aged 68, painter, veteran of civil war. He first consulted me in July, 1907. He had an irregular lesion, about 4 cm. in diameter, just anterior to and on a level with the right ear, gradually increasing in size during the past six months, and with no tendency to heal. There had been no special treatment

Fig. 7.—Case XII. Lump in breast. Before treatment.

for a malignant ulcer, it being treated as an ordinary one. The pathologist's report was that it was an epithelioma of a fibrous character. The edges of lesion were thickened and rounded, with a marked destruction of subcutaneous structures. There was no history of traumatism, but much exposure to the sun and weather. The patient gave a history of long bleeding following cuts or scratches, and this proved to be the case during treatment, bleeding from a needle puncture often persisting for fifteen minutes or more; and in August, 1907, he spent a week in the local hospital after a copious and unexpected haemorrhage from the lesion. There was difficulty in forming a firm slough, owing to a tendency for a haematoma to be formed after an injection; but when granulation set in healing was uneventful. After twelve months the cicatrix is soft and flexible and appears likely to be so permanently. Patient has recovered his health fully and is following his occupation.

CASE II.

Thos. G., aged 78, West Chester, U.S.A. Labourer. Veteran of war between the States. He said that for ten years he had had sore on left shoulder, which would respond but poorly to treatment. On examination I found a rather poorly nourished patient, general health much below par; a large pear-shaped superficial epithelioma over left shoulder, having its base at the spine of the left scapula and extending below the lower border of the clavicle, forming an ulcer the size of a man's hand, with a small island of undestroyed skin near the centre. From time to time the ulcer had been curetted, cauterized with nitric acid, and treated with astringent and mild caustic powders in an effort to heal it up, but never with more than slight success. On July 20th, 1906, I began to apply locally a saturated solution of potassium bichromate, repeated at irregular intervals, for although his treatment was entirely gratuitous, he never could be induced to report at regular intervals. In about five weeks a firm thick slough had formed, covering the entire ulcer, with the exception of the small island in the centre. After this he reported but once in two months, at the end of which time the ulcer was entirely healed to the centre point, where there was a firm scab; this is well shown in a photograph taken at that time. The newly-formed skin was very soft and pliable, well supplied with blood vessels, and more resembling normal skin than cicatricial tissue. He was ordered to report regularly to have this centre spot treated, but failed to do so. On my inquiry in November, 1908, he reported that this spot promptly forms a

dry scab, but that he daily knocks it off by carrying a shovel on that shoulder when following his occupation; the area of reformed skin retains its soft, adherent character.

I cite this case to show the penetrating properties of potassium bichromate, and the ease with which these rodent ulcers can be removed, without the patient's losing a day's work. I much regretted the intractable nature of this patient, for it entirely prevented me from observing the rapid growth of new skin over such a large area.

CASE III.) SCITAVANBO

Thomas F. G., of Philadelphia, U.S.A., aged 48; occupation, contractor. Father died at 52 years, heart trouble; mother living, aged 70, healthy; brother killed on railroad; six brothers and sisters living, all healthy. No known cancer in family on either side. Patient lost one leg in railroad accident. First noticed fever blister on lower lip about November, 1905, which did not heal up. In July, 1906, he went to the Samaritan Hospital, where his disease was diagnosed as an epithelioma, and was treated by x rays for three months. The surface healed up, but he had a hard callus underneath, which was sore much like a boil. On November 10th, 1906, he consulted a Philadelphia cancer doctor, who applied four plasters between that date and March, 1907; but the growth steadily got worse, half of the lower lip being now involved. Early in April, 1907, he entered a cancer sanatorium on the Upper Hudson, New York State, and was treated by plasters for six weeks; but the growth began to increase at an alarming rate, and the patient, becoming discouraged, returned home to consult his family. On May 22nd I saw him, in consultation with Dr. Macfarland, and found that the growth involved the whole

Fig. 8.—Case XII. Lump in breast. After treatment.

of the lower lip and the chin to the lower border of the jaw, also extending around the left angle of the mouth and upper lip for half an inch. In the left cheek, and firmly attached to the caudal-like mass on the lip, was a gland-like mass of about the size of a large grape. The discharge was extremely offensive, and it was impossible to prevent its entering the mouth.

At this time (December, 1908) the patient is in the best of health; the cicatrix is soft and pliable, and abundantly supplied with blood vessels, and there is but little deformity.

THE foundations of a medical institute for the education of women have been laid in Odessa.

A BILL has recently been introduced into the Pennsylvania State Legislature providing that a marriage licence shall not be issued until each of the applicants shall present to the clerk a certificate from an authorized practitioner stating that, to the best of his knowledge and belief, the person applying for the licence is not afflicted with pulmonary tuberculosis, epilepsy, insanity, imbecility, idiocy, or other hereditary disease.

THE SCIENCE COMMITTEE OF THE British Medical Association.

REPORT CXII.

OBSERVATIONS ON THE PHYSIOLOGY OF THE FEMALE GENITAL ORGANS.

BY
W. BLAIR BELL, and PANTLAND HICK.
M.D., B.S. LOND., M.B., B.S. LOND.,
ASSISTANT GYNAECOLOGICAL MEDICAL REGISTRAR,
BURGESS, ROYAL INFIRMARY, ROYAL INFIRMARY,
LIVERPOOL. LIVERPOOL.

II.—MENSTRUATION.*

OUR work on menstruation has for the most part been taken up with investigations into the relationship existing between this function and the calcium metabolism, and we have used in our deductions facts and observations which we demonstrated in connexion with the general calcium metabolism—alluded to in Paper I—as well as those which we now present as the result of our experi-

First of all, then, we examined the systemic blood of three hens on consecutive days for about a week. We stipulated that one at least should be a non-layer for a control, but otherwise we were unaware of the eggs laid until the experiment was completed, although, of course, our charts soon gave us an inkling of what was happening.

From the charts which illustrate the results obtained it will be seen that the first, or control hen, showed practically no changes in the calcium index from day to day. The second hen, laying every other day, showed a marked drop after laying an egg, with a big rise the next day in preparation for the laying of an egg on the alternate day. The third hen was very interesting. An egg was laid on the first day and the index was low. This index remained low for several days, consequently no egg was laid, but finally the index rose and remained so high that an egg was laid on every day during the rest of the observation. The calcium content may have dropped for a short time after the laying of the egg, but the fall was of such short duration that it was not observed—a rapid rise, or maintained high index, being necessary for daily egg laying.

We should like to hazard the suggestion here that the well-known vaso-dilatation which occurs in the combs and wattles of laying hens is due to the drop in the calcium content of the blood whereby a sort of chilblain condition is produced.

Fig. 1.—Systemic blood of hens—calcium indices.

mental and histological researches into the physiology of the function itself.

As one of us (W. B. B.) has already stated, the idea of some such relationship existing was engendered by morphological considerations in regard to certain egg-laying species, especially birds, which excrete lime salts in large quantities during this process from the calcium chamber, or lower part of the oviduct.

It has been asked why we used birds in these experiments. The answer seems so obvious that we are afraid we may have mistaken the point of the inquiry. Hens were used because we presume that no one will deny that they do excrete calcium in this way, and we thought that if we could prove certain histological and experimental analogies between the oviducts of hens when laying and human and other mammalian uteri when menstruating, we should have done all that could be reasonably required to prove the hypothesis we had set forth—apart from further evidence, of a more clinical nature, we are prepared to offer.†

* Based upon a paper read by W. Blair Bell before the Gynaecological Section of the Royal Society of Medicine, July 9th, 1909, "Menstruation and its Relationship to the Calcium Metabolism."

† We may call attention also to the fact that the lowest known mammal (*Monotreme*), the ornithorhynchus, lays calcium-coated eggs. Truly one can furnish us with a female specimen of this rare creature we shall be extremely pleased.

Fig. 2.—Systemic blood calcium indices during vicarious menstruation.

Now these experiments are very important, and we think that the result was only what one would be reasonably led to expect if the matter were considered at all.

It has been stated by Dr. Amand Routh when discussing the paper of one of us,† that he "could not see the force of the charts showing the variations of the lime in the blood of the hen which laid eggs on alternate days, for the time for any particular egg was required not on the day before it was laid, but several days before; and many eggs were in the process of development all the time." Now we cannot see where an explanation is required. Surely a comparison between Chart 2 and Chart 3 (Fig. 1) makes matters quite clear. If the hen is to lay every day, it must maintain a high index, with at most a drop for a few hours. If it cannot do this, it will only lay when it has the requisite high blood content which in Chart 2 occurred on alternate days. In these experiments the eggs were, as is usual, laid in the morning, and the blood estimated in the afternoon. Further, in reference to the statement that many eggs are in the process of development at the same time, we would point out that this is only true of the ovum and yolk sac, and that only one egg receives the further coverings of albumin and

shell at one time, these processes being completed in a few hours.

We will now deal with some facts and experiments which are of themselves just as convincing in regard to animals and the human subject. Having got the idea

tively, in that the content dropped to one-sixth of the previous amount.

It is not easy to obtain the chart of an absolutely normal menstrual cycle. We hardly remember seeing a woman who was without a single symptom at this period; but

Fig. 3.—Systemic blood calcium indices during menstruation, with hystero-epilepsy.

in regard to the existence of some connexion between the calcium metabolism and the female genital organs it of course at once struck us how easy it was to explain on this theory the fact that menstruation is nearly always in abeyance during lactation, for we know what an important and physiologically predominant ingredient of milk calcium is. It was easy to understand, too, why menstruation should frequently be absent in the debilitated, since we had already observed the important part the calcium salts play in the repair of diseased structures,² and that this form of amenorrhoea is invariably cured by the administration of lime salts; and why this function only commences when the economy has lime salts to spare from the constructive claims of the body.

To come to the actual observations on women. First, in regard to the systemic blood. There is always a very marked drop in the calcium content just before the menstrual bleeding commences. Often this drop is preceded by a marked rise (compare Reference ²). The accompanying chart (Fig. 2) illustrates both of these points. It is the chart of a girl who is subject to haematemesis each menstrual period—a true case of coincident vicarious haemorrhage. We had her in hospital some time under observation.

The next chart (Fig. 3) illustrates the systemic blood content in another class of case. The patient was suffering from minor hystero-epilepsy, due to calcium deficiency, and was completely cured by the judicious administration of calcium lactate. Her premenstrual index was low. With the onset of bleeding, which only lasted for twenty-four hours, there was a marked drop. Though not so apparent as in the last case, it is almost as great rela-

Fig. 4.—Systemic blood calcium indices during normal menstruation.

the third chart (Fig. 4) illustrates what we consider to be as normal a chart as it is possible to obtain from the human subject. In this one sees a slight rise followed by a drop—in some cases one sees two or even three abortive attempts, as it were—a further rise follows, then a big drop occurs with the onset of menstruation and any attendant symptoms the woman may periodically suffer from. In this case the patient suffered from pain and vomiting. As has been already pointed out elsewhere, it

is important that the blood should be taken for the estimation of calcium at the same time each day.³

There is, then, a marked drop in the systemic blood calcium content of the human subject, which is most marked just before the bleeding occurs. In the same way, the formation of an egg leads to a depletion in the systemic blood of birds; and in considering this we were next led to examine the excretion of the uterus during menstruation.

At the very commencement of menstruation the discharge is largely composed of leucocytes, and this local leucocytosis, which usually precedes the actual bleeding, is extremely interesting. For an examination of the discharge at this period by the method for calcium estimation mentioned shows that there are not only a

Fig. 5.—(x420). Menstrual discharge, first day; leucocytosis.

large number of free crystals, but also a far larger number precipitated within the white corpuscles themselves (Fig. 5). This was so surprising to us that we should have hesitated to give credence to what we saw, or thought we saw, or to have drawn deductions therefrom, had not other more authoritative observers than ourselves kindly examined the specimens and agreed with us. Professor J. E. S. Moore informs us that in some of the

lower forms of life excretion is carried out by means of leucocytes which may come to the surface and be thrown out, or even go back after discharging their contents.

Now this is probably an instance of what has been called pinocytosis.⁴ We have to thank Dr. R. J. M. Buchanan for calling our attention to this subject, which he did after one of us had stated elsewhere² that it was probable that the leucocytes absorbed the calcium in a fluid form, and carried it from the glands to the exterior, possibly preventing a free secretion of calcium compounds which might increase the coagulability of the blood *in utero*. We shall allude to this point again in a moment.

An examination for calcium salts in the menstrual discharge at a later period—third to fourth day—shows that there is still a marked excess as compared with the systemic blood; but the discharge is then sanguineous and contains the usual vaginal epithelial cells with but a few leucocytes, and it shows a marked tendency to clot (Fig. 6). Thus it will be seen that there is an excretion of calcium coincident with the fall in the blood of the calcium content.

Further, to prove these views we tied the uterine horns of rabbits and examined the contents. The fluid thus collected was found to be exceedingly rich in calcium—more so in the adult menstruating rabbit than in the virgin. In Fig. 7 is seen the fluid collected from a young

uteri of women and rabbits were next examined histologically.

We found, as others have done, that there is a marked activity in the glands at this time, with a diapedesis of leucocytes in the neighbourhood. In Fig. 9 is seen a section of the menstruating rabbit's uterus under a low power. In Fig. 10 a gland from the same section is shown under a high power. It is a gland in a state of activity. Leucocytes are seen outside the gland, and in the process of making their way between the gland epithelium. To this we would call special attention. It will be noticed that they become elongated and flattened. They were recently observed and figured by Marshall and Jolly⁶ in this condition, but these observers concluded that these elongated cells were merely gland epithelial cells in an actively secreting condition. Ernst Holzbach⁵ also mentions the same cells, and comes to the same conclusion as Marshall and Jolly.

Lastly, it will be observed that there is a collection of leucocytes within the gland lumen, embedded in the secretion of the gland. We believe that these leucocytes then carry some calcium compound with them to the exterior. Apparently the columnar epithelium that lines the interior of the uterus plays the same part as that lining the glands, which are formed by a process of invagination from the surface.

In Fig. 11 the same thing is seen happening in a gland from a menstruating woman's uterus. We have not space

Fig. 6.—(×420.) Menstrual discharge, third day.

Fig. 7.—(×420.) Fluid from artificial hydrometra of young virgin rabbit.

non-menstruating virgin rabbit. Here one finds the calcium combined or mixed with mucin with which it is precipitated. In the older menstruating rabbit it exists in larger quantity, free, as well as with the mucin and leucocytes, as is seen in Fig. 8.

We may here mention that the secretion from the Fallopian tubes contains very little calcium in comparison with the quantity secreted by the uterus. We performed several experiments to test this point.

To complete the chain of evidence the menstruating

Fig. 8.—(×420.) Fluid from hydrometra of menstruating rabbit.

here to discuss the other points of histological interest, for they are many and somewhat controversial. But we cannot pass on without illustrating the histological analogies to be observed in the calcium chamber of the hen. In Fig. 12 is seen a section (low power) of the calcium-secreting chamber of a non-laying ("sitting") hen. In marked contrast with this is a section under the same power—shown in Fig. 13—of the calcium-secreting chamber of a laying hen. In the former the *rugae* or papillae are small, and the stroma underlying the epithelial

layer full of cells which have hardly any definite glandular formation (as is seen in Fig. 14). In the latter (Fig. 13)—from the laying hen—the *rugae* are large and there is a great regularity of actively-secreting glands, as will be seen in the high-power sections (Figs. 15, 16, and 17).

In Fig. 15 there are two points of interest to which we attach some comparative importance. At one spot is seen a rupture in the continuity of the epithelial surface, such as can be seen in one place in the menstruating rabbit's

considered in order to get on to *terra firma*, and into a region from which we can glean facts of importance from a clinical point of view. In the first place, let us briefly consider the periodicity of menstruation and its significance. From the very earliest times this periodicity has been the subject of much mystery, more speculation, and not a little unconscious humour. As a result the periodicity has been allowed to form the chief stumbling-block to a solution of the problem which has been so long *sub judice*.

Fig. 9.—($\times 250$.) Menstruating rabbit's uterus.

uterus (Fig. 9), and directly opposite to this is seen the secretion collected and infiltrated with leucocytes outside the mouth of a gland, a condition frequently seen in the menstruating uteri of women and rabbits, and, we suppose, in other mammals.

Fig. 16 shows an invagination forming a superficial gland in the calcium chamber through the epithelial cells of which leucocytes may be seen passing. Fig. 17 illus-

Fig. 11.—($\times 1200$.) Menstruating woman's uterus showing glandular activity.

And yet after all there is no mystery, nor is there anything supernatural or obscure about what regularity there may be in the appearance of the catamenia. We have ceased to wonder at the rhythm of respiration and cardiac contraction—we now know that the basis of all the causative factors is founded upon chemical changes—anabolic and katabolic in nature—and that these changes themselves are entirely dependent for their regularity upon the

Fig. 10.—($\times 1200$.) Menstruating rabbit's uterus showing glandular activity.

trates the vascularity and diapedesis which is seen in these *rugae* when actively engaged. Figs. 15 and 17 were taken from a hen while an egg was in the process of being coated with lime salts.

Since it has recently been established by Heape⁷ and others that the pro-oestrus stage of the "rut" in animals is really analogous to the human menstruation, these facts are of considerable importance, and we think sufficiently demonstrate the cause and effect we wish to emphasize.

There are, however, a few other points which must be

Fig. 12.—($\times 250$.) Calcium-secreting chamber of a laying hen.

general metabolism in whole or in part. However little understood or insufficiently explained there is little doubt that other factors are merely correlated.

The periodicity of the menstrual function—of the "rut" and breeding in animals—is exactly on the same lines. Merely a question of whether or not certain necessary articles—among them calcium—are at the disposal of the organs concerned for excretion at certain times. To some extent Stevenson⁸ argued on the same lines in discussing his "menstrual wave" theory in very general terms. This

periodicity has really no immutable law of a fixed time, as one might be led to think by the way some authorities have written of it. It is subject to many influences, for the individual has first claim upon all ingredients necessary for herself before she has any to spare for excretion—that is, for supplying a fresh individual (her embryo) or for menstruation. These influences, apart from pregnancy, are seasonal and climatic, dietetic and hygienic. How important they are can be gauged by the effect evolution

secretions of the ductless glands, and it may be worth while, therefore, to mention briefly the part which these secretions may play in the economy of this function. In the first place, let us point out that clinically we have used the calcium salts with very good results in the following classes of cases:

1. *Amenorrhoea* from general debility of a chronic nature, but more especially that resulting from acute diseases, such as influenza, in which the exhibition of

Fig. 13.—($\times 250$.) Calcium-secreting chamber of a laying hen.

has had, or even by the effect domestication has upon the habits of wild animals and civilization upon the human race.

The periodicity of the catamenia is, then, merely the result of a concomitant series of metabolic processes—such as are seen in other spheres of physiological activity—which may or may not allow of regular menstruation. We do not think we need go further into this point; it

Fig. 14.—($\times 1200$.) Tip of ruse from calcium chamber of non-laying hen.

seems to us to be very obvious, and if viewed in this light makes a strong argument for our ideas concerning this influence of the calcium salts in particular.

As already mentioned, we have come to the conclusion that the calcium metabolism is largely influenced by the

*The interesting fact, which has been overlooked or underestimated by most students of menstrual periodicity, of repeated coitus (every fortnight in rabbits) in unimpregnated animals is surely comparable to the monthly menstruation of non-pregnant women. That this condition is not more frequently observed in animals is due to the promptness with which impregnation usually occurs.

Fig. 15.—($\times 1200$.) Ruse from calcium-secreting chamber of laying hen.

calcium (in doses of 30 grains of calcium lactate every other day) not only relieves the amenorrhoea but also the symptoms ("nervous headaches," etc.) associated with the debilitated state of the patient.

2. *Menorrhagia* due to what are called "constitutional" conditions; that is to say, where there is no local pathological manifestation. We explain this paradoxical position in regard to amenorrhoea and menorrhagia in the

Fig. 16.—($\times 1200$.) Superficial gland in calcium chamber of laying hen.

following way: In the first class of cases there is not sufficient calcium at the disposal of the economy for menstruation, and in the second, that though there is enough for menstruation the blood content does not rise rapidly enough to stop the flow.

Now, it is a matter of common observation that, in young girls especially, the thyroid enlarges in the majority of cases just before the onset of menstruation—that is to say, when the blood calcium content is high. With the enlargement the onset of bleeding soon follows. Inci-

dently, it may be mentioned that a similar enlargement of the gland occurs early in pregnancy, when the menstruation is suppressed, and before the fetus can utilize the amount of calcium at its disposal in the blood. We have also observed this thyroid enlargement in artificial menopause.

The function of the thyroid secretion in this respect is to stimulate calcium excretion, which may take place from the uterus, or, failing that, from the kidneys or by the bowel. In this way thyroid may be a valuable drug—indeed, it has often been so used—in amenorrhoea.

In the same way, we believe that the internal secretion of the ovary has the property of depleting the blood and tissues of calcium salts, and possibly a special action in stimulating excretion by way of the uterus.

We have in opposition to these the secretion of the adrenals, and probably that also of the pituitary gland. Both, as will be shown in a subsequent paper, act in a similar manner upon the uterus, especially when in the pregnant state. But, as regards their influence upon menstruation, the extract of these glands assists in the production of uterine contractions which are marked at that time, and also in other more obscure ways from their relationship to calcium metabolism in general, and in particular that of menstruation.

Fig. 17.—Vascularity and diapedesis in calcium chamber of laying hen.

Further, with regard to the secretion of the pituitary body—we have at present little direct clinical evidence in regard to the adrenals—it has been shown that tumours of, and in the neighbourhood of, the pituitary gland cause amenorrhoea, and that cessation of the menses is one of the earliest symptoms of acromegaly.⁹ It has also been shown that sexual infantilism with an absence of menstruation is a general complication in early disease of the pituitary gland.¹⁰ An analysis of about 150 cases of acromegaly recently made confirmed the above statement regarding amenorrhoea, and also that lactation hastens the progress of the disease.¹¹

CONCLUSIONS.

1. That menstruation is a periodic function only in so far as the calcium metabolism is in harmony with this periodicity, and that the function is dependent upon the calcium metabolism in all its ramifications.

2. That the haemorrhage into the Graafian follicle may be coincidental, and is probably the result of the lowered coagulability of the blood or vasomotor changes; but that rupture of the follicle is in no way responsible for menstruation.

3. That the bleeding from the uterus, while due to the lowered coagulability of the blood in part, is also dependent on the local changes in the capillaries from which the diapedesis of leucocytes and corpuscles occurs; and, further, that these leucocytes are an active factor in the conveyance of calcium salts from the glands to the exterior.

4. That the uterine glands excrete calcium and mucin, and that therefore the uterus is a "menstrual organ."¹²

5. That there is a correlation between the ovaries and uterus in reference to menstruation, but that the ovary is probably no more predominant than other ductless glands in this respect.

6. That menstruation *per se* is not a necessary adjuvant nor concomitant to fertility and reproduction.

OBSERVATIONS ON PLEURAL PAINS AND ADHESIONS.

By JOHN T. MACLACHLAN, M.D.

ASSISTANT PHYSICIAN, GLASGOW ROYAL INFIRMARY.

EVERY physician is called sooner or later to treat cases of phthisis pulmonalis, which, notwithstanding all the methods of treatment introduced since Koch announced his brilliant discovery of the tubercle bacillus in 1882, still remains one of the most deadly diseases known. The disease is undoubtedly curable in its early stage; but that stage is only too frequently allowed to slip past, ere the patient, his friends, and perhaps his medical adviser, realize the exact position of affairs.

Clinical observation warrants, I think, the conclusion that phthisis pulmonalis may begin in one of three ways: Firstly, as pleurisy; secondly, as bronchitis; and, thirdly, as a caseating pneumonia, or the deposition of tubercle in the substance of the lung with bronchopneumonia. The second and third modes of origin are well recognized, but the first is not sufficiently appreciated.

Patients often complain of shooting or darting pains in the chest long before tubular breathing or expectoration reveals the presence of serious mischief in the lungs. These darting pains are too often ascribed to what has been called pleurodynia or intercostal neuralgia, because no physical signs have been discovered to denote the presence of pleurisy. I assert, after four years' careful observation, that the so-called pleurodynias are in reality localized patches of pleurisy, and I infer that they are mostly, if not always, of tuberculous origin. These sharp pains in the chest come on suddenly, without reference to wind or weather. I do not wish to deny that rheumatism may attack the pectoralis major or the latissimus dorsi; but the pains I refer to are not, in my opinion, of a rheumatic nature.

Of 300 patients who came to the Dispensary for advice, 50 complained of sharp pains in the chest. Their ages ranged chiefly from 20 to 40 years; although younger people and older people were not exempt. The pains were referred to certain well-defined regions, namely, where the lungs divide into their lobes, or the free margins of the lungs. Thus, the pains were often referred to the right nipple, either a little above it or below it; to the left border of the heart; frequently to the lower left axillary region, corresponding to the division between the upper and lower lobes of the left lung; and to points a little below the apex of each scapula.

The involved areas may be diagnosed by very delicate percussion, which may be called tactile percussion, as the sense of resistance is strongly appealed to. The ordinary stroke in percussion strikes through those areas of pleurisy patches and brings out lung resonance. The fingers of the left hand are placed flat on the chest. The tip of the middle finger of the right hand is the plessor, and it should not be raised above 1 or 2 in., and then brought down on the surface of the middle finger of the left hand. The percussing finger should be kept at an easy angle, and should move from the knuckle-joint, the wrist being kept steady. If this method of percussion be practised for several weeks or a few months, it will be

possible when percussing a patient's chest to detect or at least suspect areas of superficial dullness where there have been localized pleurisies which have left adhesions as a permanent memorial.

Sometimes patients can corroborate the diagnosis by remembering the sharp pains they felt at the involved sites, and sometimes they do not recollect having any suffering. From this, and for other reasons, I conclude that children often have attacks of pleurisy which are overlooked. Such vestiges of a bygone pleurisy seem to me to occur most frequently low down on the left side, over the axillary portion of the lower lobe of the left lung.

Auscultation is not nearly so valuable as percussion in diagnosing such superficial areas of dullness on the surface of the lung. Occasionally the affected area may not be much larger than a square inch, as I have once verified *post mortem* in a case in which the adhesion was in the vicinity of the right nipple. If the fibrinous exudation is recent, rubbing, grating, squeaking, or creaking sounds may be heard. If the dullness is considerable, the inspiratory murmur may be fairly distinct; and the expiratory murmur faint, and preternaturally short, as compared with that over sound pleura and lung. Probably this indefiniteness of the respiratory murmur may be due to the lung being adherent to the chest wall, and its natural recoil interfered with by the adhesions.

Inspection in well-marked cases of pleural adhesions may show deficient expansion and contraction. It is not practicable to diagnose adhesions in the scapular regions, or even in very obese subjects, except by inference.

The diagnosis of pleural adhesions should be regarded as a danger signal to warn the patient to take all precautions in his mode of life, diet, etc., to ward off the graver manifestations of tubercle in the lung.

The immediate treatment of fibrinous pleurisy consists in the internal administration of sedatives, such as opium, and the use of counter-irritants. These measures will not banish old adhesions, but they relieve recent attacks of pleurisy.

It does not follow because a patient has had an attack of pleurisy that he will fall a victim to phthisis pulmonalis. Indeed, were such the case, every fourth, or at least every sixth, patient would develop the disease. It is the exception rather than the rule. But the two conditions are so frequently found together that they appear to me to have a common origin; and phthisis pulmonalis develops after a history of localized pleurisy so frequently that the latter rises into great significance.

When a patient comes to the dispensary complaining of his chest, I always put the three following questions, and subsequently other questions that arise out of the answers given.

Have you a cough?

Have you any spit or expectoration?

Do you suffer from any sharp pain in the chest, referring particularly to the common sites indicated above?

It is necessary to be wary in inquiring about a cough, as consumptive patients are very shy of admitting a cough, while emphysematous patients are often silent about their morning cough, although desirous of being relieved of their shortness of breath. If a patient complains of having had for a considerable period a cough and spit, without ever having had any sharp stitches about the chest, he is probably suffering from bronchitis. If he complains of cough, spit, and sharp pains in the chest (not the pain at the pit of the stomach due to hard coughing), he has, almost to a certainty, got phthisis pulmonalis. Cancer of the lung, however, is one exception. The cough indicates the presence of a foreign element in the respiratory tract; the sputum, if it be purulent or muco-purulent, points to bronchitis or bronchopneumonia being present; and if the sputum contains little cheesy-looking particles, these will denote that caseation is going on in the lung or lungs; the sharp pains will point to pleurisy, so that the three cardinal signs or symptoms—cough, pain, and expectoration—will in all probability correspond to bronchitis, pleurisy, and tuberculous pneumonia, and, in a word, phthisis pulmonalis.

I have pleasure in stating that Mr. E. Wardman Wilbourne, medical student, who has been working with me at the dispensary, has frequently verified the above observations, and agrees with the conclusions drawn.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

AVULSION OF A FINGER.

THE following accident appears to me to be sufficiently remarkable, both in the manner of its production and its effects, to be worth recording. The patient, a young man, was indulging in a form of amusement euphoniouly entitled by the proprietor "swooping the swoop," a looped metal contrivance running by means of a

The finger, with its tendon, shown against a cardboard background.

wheel along an inclined cable. The amusement consists in grasping the horizontal bar of this loop and while thus suspended having an aerial journey along the cable. On reaching the lower end one lets go and drops two or three feet to the ground. The patient had a ring on the little finger of the right hand. On attempting to let go, the stone in the ring, which had slipped round to the palmar aspect of the finger, caught in the junction between the horizontal and vertical portion of the loop, with the result that he was momentarily suspended by the little finger, and the finger was avulsed in the following manner: The bone gave way at the joint between the second and third phalanges; the skin opposite the lower end of the first phalanx and the whole length of the deep flexor tendon, maintaining its attachment to the phalanx, was pulled completely out of the arm from its origin near the elbow, the finger being picked up off the ground with its accompanying tendon.

ACUTE INVERSION OF THE UTERUS.

I READ with some interest Mr. Holthusen's contribution to the JOURNAL of January 23rd, as during the past few months two instances of a somewhat similar nature have come under my care, being the only cases of this description I ever met with, occurring, rather singularly, within five months of each other.

One, which occurred in July, 1908, was in a primipara aged 23. The first two stages of labour were normal, but upon its expulsion the placenta was found attached to an inverted uterus, though not technically adherent. It was speedily separated with little or no haemorrhage. There was great disturbance of respiration and circulation, cyanosis, etc., in fact the patient had the appearance of imminent dissolution. On returning the uterus, which was effected with little or no difficulty, the alarming symptoms gradually subsided. The patient, who was a very healthy young woman, made a splendid recovery.

The second case happened in December, 1908, in the second pregnancy of a woman, aged 30, with hip-joint disease and a weak heart. Labour was tedious and recourse was had to instrumental delivery. On some amount of haemorrhage taking place, it was found that the vagina was occupied by the uterus as well as the placenta. The latter was easily removed, but the return of the former to its natural position was an affair requiring the exercise of some care and manipulation. What immediate after-effects there were seemed more attributable to haemorrhage, than to disturbance of the parts. The patient lived six weeks, then died from cardiac debility, anasarca, etc.

Birstwith.

H. G. HAROLD CLARESON.

TREATMENT OF OPHTHALMIA NEONATORUM.

A CHILD with ophthalmia neonatorum runs so many risks from the treatment it receives—at any rate when the treatment is not carried out by experienced hands—that I think the following remarks are in place:

As a rule the mother consigns her unfortunate offspring to the darkest corner of a dark and badly-ventilated room, and covers up its head with a cloth, which is soon contaminated by discharge. Blepharospasm confines the pus in the conjunctival sacs, and renders all manipulation not only difficult but dangerous. A strong solution of silver nitrate is swabbed on the everted lids, causing considerable pain, and perhaps injury to the cornea owing

to the blepharospasm and the desire to reach all the crannies of the conjunctival sacs.

The indications are clear. Light and fresh air must be let into the room, and the child should go out daily. The face must not be covered up; cleanliness must reign supreme. A towel should be kept behind the child's head to receive any discharge, and must be frequently changed. The nurse must wash her hands before and after the dressing. If the child's hands wander to the eyes they must be fastened down by a safety-pin through the sleeve.

To overcome the blepharospasm an external canthotomy should *always* be done. This simple operation is performed by inserting one blade of a blunt-pointed pair of scissors into the conjunctival sac at the outer canthus and with the other blade external cutting horizontally outwards. The orbicularis palpebrarum is divided, the palpebral opening enlarged, the lids can be easily and safely everted, and the conjunctival sac washed out.

Instead of silver nitrate solution I use argyrol in the strength of 25 per cent., and the nurse is instructed to drop one drop into each conjunctival sac every quarter of an hour during the day—once or twice during the night. Any discharge is washed away from the lids as soon as it collects with a weak antiseptic solution, such as solution of potassium permanganate (1 in 10,000), and three times daily the conjunctival sacs are washed out with the same solution, just sufficient lotion being used to remove any visible discharge. If there is the slightest haziness of the cornea, atropin is instilled once daily. The points to be emphasized are:

1. Cleanliness, fresh air, and light.
2. External canthotomy always to be done.
3. Argyrol, 25 per cent., one drop every quarter of an hour.

In Berlin the use of silver preparations has been in some quarters given up entirely in ophthalmia neonatorum, and a 10 per cent. ointment of aluminum acetate inserted between the lids hourly with good results, but I have as yet had no experience with this.

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF THE BRITISH EMPIRE.

FRENCH HOSPITAL, LONDON.

CARCINOMA OF CERVIX: HYSTERECTOMY, NEPHRECTOMY: RESECTION OF SMALL INTESTINE: RECOVERY.

(Reported by Mr. KENNARD, F.R.C.S. Edin., late House-Surgeon to the French Hospital.)

[Under the care of Dr. SUNDERLAND, Mr. EDMUND OWEN, and Mr. CLAYTON-GREENE.]

MADAME M. was admitted on October 3rd, 1907. She gave a history of a miscarriage three weeks previously and of occasional attacks of bleeding since then. She had had two children, the last two years previously.

On examination, a cauliflower growth of the cervix uteri was found invading the right fornix. The uterus was not enlarged, and it was freely movable.

Mr. Owen operated on October 15th, the patient being in the inverted position. The right ureter was involved in the growth and could not be separated from it. It was, therefore, cut across a little above the mass, and the lower end was taken away with the uterus and its appendages.

The renal end of the ureter was then drawn down and implanted into the side of the bladder, being secured to the fibro-muscular coat by several fine sutures. Further, in order to keep it well drawn down, so that there might be no strain on the point of union, it was fixed to the sheath

of the psoas by a couple of sutures. But in case of the implantation proving unsuccessful, a rubber drainage-tube was passed along the side of the bladder and brought out by the vagina. A gauze wick was left in the upper part of the abdominal wound. For five days everything seemed to be going well, but there was then an escape of urine on to the abdominal dressings, and next day urine was found passing by the vaginal wound. The woman seemed, however, quite comfortable. In due course the abdominal wound entirely healed. Except for the vaginal leakage she was in fair condition, and on November 10th she was sent to the convalescent home at Brighton, there being still a leakage by the vagina. On her return three weeks later she said that she felt quite well except for the leakage. Cystoscopic examination showed the left ureter working well, the right being absent. The removal of the right kidney was advised, but this she declined.

It was unfortunate that the implanted ureter failed to take up an attachment to the bladder. Everything was arranged towards this, but notwithstanding, after, apparently, a certain amount of hesitation, the ureter "carried away."

By the following March, however (1908), she had grown so weary of the leakage that she willingly came in for the nephrectomy. This was done, and an uninterrupted recovery was the result. The kidney was found soft; the pelvis and ureter were dilated. She made a rapid and complete recovery.

On April 11th the woman was readmitted, suffering from chronic intestinal obstruction, with marked peristalsis of the small intestine. It was thought that this was probably due to adhesions having formed between the small intestine and the uterine stump. The symptoms becoming very acute, and Mr. Owen being absent, Mr. Clayton-Greene operated on April 24th, making an incision through the right semilunar line. On exploring the abdominal cavity, a hard lump was felt in a coil of small intestine; this was brought up to the surface, and was found to be a mass of new growth of the size and shape of a moderate-sized Murphy's button. The intestine was much distended. It was not thought safe to excise the growth without providing efficient drainage. A lateral anastomosis between the two arms of the loop was therefore performed well away from the growth, and the mass was then protruded through a separate opening in the loin, the anterior wound being closed. The segment of bowel containing the malignant growth was then excised, and a Paul tube was inserted into the proximal piece of intestine, the distal end being closed. No enlarged mesenteric glands were discoverable. The intestine drained freely through the tube, and before long the lateral anastomosis became functional, and the discharge of faecal matter was reduced to an occasional stain on the dressing. The anterior wound healed by first intention, and the opening in the loin gradually closed.

The object in performing the operation in this manner was to avoid the risk of suturing the intestine while in a distended state, without at the same time providing adequate drainage; it was also thought better to complete matters, if possible, at one operation, rather than to be compelled to resect an artificial anus subsequently, having regard to the previous surgical experiences of the patient. The woman reported herself at the hospital in January last as being in perfect health and as having increased considerably in weight.

Histological Examination.—Dr. B. H. Spillsbury states that the growth is a squamous-celled carcinoma in the submucous coat of the intestine, "which is suggestive of its being secondary to the uterine tumour." This report is in accordance with the opinion formed at the time of the operation. It might have been expected that such a growth would have arisen rather by implantation on the peritoneal surface, but this certainly was not the case. The tumour in the intestine was freely movable in the abdominal cavity, and it bore no relation to the uterine region. The peritoneal coat was not involved, except where it was puckered at the actual site of the stricture. Moreover, the report states that the growth apparently started in the submucous coat of the intestine. Such a secondary growth, presumably the result of a vascular metastasis, must be of rare occurrence, and the fact that up to the present no other secondary deposit has been observed makes the condition still more interesting.

Sir FELIX SEMON in the Chair.

Functional Disorders of the Stomach.

DR. SIDNEY MARTIN delivered the third of the Lettsomian Lectures for 1909. Dealing with the treatment of functional cases, he said that in cases of hyperchlorhydria it was essential to give rest to the stomach by prescribing a non-irritating diet, by giving bodily rest—in the milder cases only after meals, but in the severer cases the rest must be complete and in bed. The increased acidity must be counteracted by alkalis, the best of which was bicarbonate of soda in 15 to 20 grain doses given half an hour after meals. But that alkali acted best in such cases when given with sedatives such as diluted hydrocyanic acid in 3 minims doses, and liquor morphinae hydrochloratis in 5 to 10 minim doses. Extract of cannabis indica in $\frac{1}{2}$ -grain doses and glycerine of carbolie acid in 10 minim doses also acted as sedatives, but were not so useful as the two first mentioned. When the symptoms produced by hyperchlorhydria were severe, lavage once daily for a week was highly beneficial. In cases where there was a great deficiency of secretion the treatment was somewhat different from the foregoing. In those cases rest was essential, and in all of them rest in bed for a period of five, six, or seven weeks. Without that rest no other treatment was curative. The diet must be an easily digestible one, and it was best to begin the treatment with a diet of citrated milk, gradually increasing the food by bread and butter, eggs, fish, chicken, mashed potatoes, until an ordinary diet was reached. That graduated diet was highly beneficial in such cases. It might be considered that drugs to stimulate the secretion of gastric juice would be highly beneficial in such cases, yet it was very difficult to say what drugs did stimulate the secretion of gastric juice and what were beneficial in those cases. Bicarbonate of soda in 5 grain doses stimulated the secretion. Small doses of nitro-hydrochloric acid combined with nux vomica or strychnine certainly did good in many cases. Sometimes the acid mixture was best given with one of the gastric sedatives previously mentioned, but in many cases where drug treatment seemed to be of no avail, lavage daily for a fortnight, and then at longer intervals, appeared to be the best treatment. It acted in two ways: first, by preventing further damage to the stomach function by removing the retained food; and, secondly, by stimulating the mucous membrane to secrete. The best solution to use for lavage was water containing a drachm each of bicarbonate of soda and common salt to the pint, two pints being used and the lavage being done at night. Of the foods which stimulate the secretion, carbohydrates, proteids and meat extracts were the best; fats did not stimulate the secretion. In cases associated with rapid expulsion of food from the stomach, sedatives were the most useful drugs for treatment. In cases of dilatation, besides the general treatment above mentioned, lavage was highly beneficial. Strychnine was also a useful drug given in moderation, more, however, for its general tonic effect on the nervous system than for any special effect on the stomach itself. Both those modes of treatment were very useful with well-marked dilatation. Massage of the stomach from left to right helped in cases of dilatation, as well as exercises done regularly every day, but he had not himself found that the application of electricity had any beneficial effect in such cases. Cases of nervous dyspepsia were very often treated with success by regulating the diet and mode of life, and giving a sedative alkaline mixture alternatively with a stimulant such as strychnine. Potassium bromide and valerian were also useful. Patients, however, might be quite intolerant of drugs, and it was impossible to lay down any general rules for the treatment of such cases. They had to be treated on their own merits. One case might be benefited by rest in bed, massage, and diet—a treatment which in another case might lead only to an aggravation of the symptoms. Other cases were treated by removal to other surroundings and by leading an open-air life. The cases which showed extensive vomiting and flatulence were

often well treated by means of lavage, but even in cases of vomiting lavage might be unnecessary. The prominence of reflex symptoms demanded treatment by rest more than the predominance of stomach symptoms. One important point in the treatment was that no few weeks' treatment was of any avail in such cases, if pronounced. The treatment regulating the mode of life might have to be continued for two or three years for any real benefit to be obtained.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Friday, February 19th, 1909.

Sir PATRICK MANSON, K.C.M.G., M.D., F.R.S., in the Chair.

Bronchial Spirochaetosis in India.

DR. H. G. WATERS read a paper on a species of spirochaete which he had found associated with a form of bronchitis in India. The first instance of the infection he had seen was at Tumla, in the United Provinces, where a European was admitted to hospital last year with a temperature of 104°, a cough, and a copious expectoration of bronchial mucus. No malarial parasites were present in the blood; and although a few rhonchi could be heard over the chest, no tubercle bacilli or other bacteria were found in the sputum. In looking for organisms, however, he discovered large numbers of what he thought a new variety of spirochaete. The temperature remained continuously high for three days, and fluctuated between 102° and 104.5°. He did not at first attach pathogenic significance to the spirochaetes, and attributed their presence to oral sepsis; but, on examination, they could not be found in swabs from the mouth, and there was no evidence of stomatitis, nor, in fact, any local condition to which the spirochaetes could be related. After three or four days the temperature fell to normal, and the spirochaetes disappeared from the sputum. Fourteen days afterwards, a relapse occurred with marked bronchial symptoms and similar spirochaetes reappeared in enormous quantities in the sputum. A single case, of course, furnished insufficient evidence on which to base a claim to pathogenicity; but its importance was very much increased by the fact that in the course of the next few days he saw seven more instances in the same district, in which the symptoms were exactly reproduced. The co-ordination of the clinical signs exhibited by each patient with the appearance of the spirochaetes in the sputum he thought was significant of a specific infection, and he submitted that a case for inquiry had been established. Dr. Waters's paper was illustrated by microscopic preparations of spirochaetes in sputum.

DR. C. W. DANIELS said that the important point about Dr. Waters's paper was the fact that the peculiar symptoms had been seen in a number of cases. One saw spirochaetes in so many non-pathogenic discharges and exudates that there was rightly a good deal of scepticism about their pathogenic function. It might well be that spirochaetes in sputum were accidental parasites of enlarged and unhealthy bronchi; but the fact that there was a definite type of illness, and especially that there was a series of cases in which they occurred, was interesting and suggestive.

DR. G. C. LOW agreed with the last speaker. The pathogenicity of spirochaetes was difficult of proof because they could not be reproduced in cultures. Had Dr. Waters looked for pneumococci as well as for other organisms associated with lung trouble?

DR. WATERS, in reply, said that he had found no pneumococci in the sputa. There were, of course, the usual septic bacteria, but in his cases the sputum was always characteristic so far as regarded the spirochaete, and the possibility of the organism being pathogenic he had accepted only after very careful consideration.

Endemic Disease in Barbados.

DR. T. FAUSSET MACDONALD communicated several notes on tropical diseases in Barbados, in which he said that for a tropical station the island was generally supposed to be exceptionally healthy. No doubt there was much truth in that statement, but there were elements of doubt. One important question was whether yellow fever ever occurred in Barbados. Medical opinion was divided about a class of cases in which there was high fever, occasional black

vomit, and other serious symptoms. Some considered the disorder to be true yellow fever, others thought it was epidemic icterus, while others again believed that it was nothing but severe influenza complicated with jaundice. Still another disease about which there was great uncertainty was an affection which was diagnosed by some authorities as sprue and by others as pellagra. It had been called *psillos pigmentosa*, but he himself believed it to be pellagra.

Dr. G. C. Low agreed that the cases spoken of by Dr. MacDonald were pellagra; they were certainly not sprue, and they had little resemblance to that disease. Yellow fever was notoriously difficult of diagnosis. It might be almost impossible to differentiate it from malignant malaria, which was often complicated by hæmorrhages from the stomach and intestines. Severe, and even fatal, cases of obstructive or idiopathic jaundice were common in the West Indies, but he himself had never heard of epidemic jaundice in Barbados.

Yellow Fever in Brazil.

Dr. E. RIBAS, Director of the Sanitary Department of San Paulo, Brazil, read a paper in which he stated that an extensive series of experiments at San Paulo had fully proved the accuracy of the work of the American investigators in Cuba. There could now be no further doubt that yellow fever was propagated by *Stegomyia fasciata*, in all probability by *Stegomyia fasciata* only, and that fomites or other agencies had no influence in disseminating the disease. In one experiment which he made he procured larvae of that mosquito at San Paulo, the city being then quite free from yellow fever, and sent them to a centre where the disease was raging. The mosquitos hatched from the larvae were allowed to suck blood from a patient there who was seriously ill with yellow fever, and were then brought back—360 miles—to San Paulo, where they were induced to bite six healthy persons, of whom he himself was one. In three instances there was no result, but in the other three typical symptoms of yellow fever developed. It was important to note that of the three people who resisted the disease successfully one was himself, and the other two were medical men who had been associated with him in dealing with many epidemics of yellow fever in San Paulo. The three patients in whom yellow fever developed were Italian immigrants who volunteered for the experiment, and happily their infections were not malignant. He believed that as they had just arrived from Europe they were, for that reason, less immune than old and seasoned residents. In all the cases there was an incubation period of sixteen days. Dr. Ribas illustrated his paper by lantern slides showing the mortality from yellow fever in various towns in Brazil, and proving that in every instance epidemics had been stamped out by the rigorous extermination of mosquitos and the simultaneous adoption of general sanitary measures.

Dr. LOUDON STRAIN said that he could personally confirm everything that had been said by Dr. Ribas. The mortality in Santos and San Paulo before mosquitos were known to convey the disease was appalling; but, since the campaign against yellow fever had been undertaken on scientific lines, the cities of Brazil had entered on a new era of prosperity. In Rio, Santos, and San Paulo—all of which were, formerly, terribly insanitary—the public health might now be described as satisfactory.

Dr. C. W. DANIELS said that these results were striking, but, although he did not doubt the influence of *Stegomyia* in the spread of yellow fever, he would point out that in British Guiana, where no systematic attempts had been made to exterminate mosquitos, yellow fever had spontaneously disappeared. General experience led to the belief that, during a period of about thirteen years, there was comparative immunity from epidemics of yellow fever, but at the end of that time the disease broke out anew, and raged for two or three years, until it exhausted the susceptible individuals in the community. He thought the same belief was current in Barbados and other West Indian islands.

Dr. C. F. HARRORD asked why Dr. Ribas classed as immune individuals who had not themselves suffered from yellow fever. Did residence in a city where the disease was prevalent confer immunity?

Sir PATRICK MANSON said that these facts possessed much

interest and importance. One peculiarity of yellow fever was the immunity of the Creole. We knew why natives of the tropics were immune to malaria: they suffered from the disease as children. Was this paralleled by yellow fever? If so, it followed that that disease must be endemic.

Dr. RIBAS said that the susceptibility of new arrivals was undoubted, but it was difficult to explain. Immigrants arriving at Santos in the yellow-fever days were hurried through the port so as to get them as quickly as possible to their destination; but a stay of four or five hours in Santos was often sufficient for infection. This preference might be accounted for partly by the fact that mosquitos bit blacks much less freely than new arrivals; but it was also true that the natives had no immunity as regarded other diseases. For instance, epidemics of cholera had generally been more fatal to blacks than to the European residents in Brazil.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

Tuesday, February 23rd, 1909.

T. H. GREEN, M.D., F.R.C.P., in the Chair.

Chloroma.

Dr. DE HAVILLAND HALL and Dr. HEBB presented a communication based on a case of chloroma which had been in the Westminster Hospital.

The patient was a girl, aged 4 years and 3 months. The illness commenced one month before admission with irritability and pain in the head. A fortnight later a lump developed on each side of the neck, the eyes became more prominent, and the veins over the temporal region were distended. On admission, in addition to the above, there was facial paralysis on the right side, and the patient was very anæmic. On December 12th, double optic neuritis was noted. The patient gradually became weaker and more anæmic and died on December 24th, 1907. The blood was examined on five occasions. On admission, red corpuscles 4,100,000, leucocytes 40,600, 85 per cent. of which were monomorphonuclears. Hæmoglobin 60 per cent. The day before death red corpuscles were 1,140,000, leucocytes 23,900, equally divided between polymorphonuclears and monomorphonuclears, and 12 per cent. of eosinophilous myelocytes. The hæmoglobin had fallen to 18 per cent. As was usual in these cases there was nothing characteristic about the temperature chart; there was usually slight pyrexia, the highest temperature recorded being 102.4° F. Arsenic and iron were given without influencing the course of the disease.

The diagnosis was based on the anæmic appearance of the child, the masses in the temporal region, which even during life had a greenish tint, and the protrusion of the eyeballs. The examination of the blood also helped to confirm the diagnosis, as there was a leucocytosis affecting the large lymphocytes. At the necropsy chloroma growths were seen in the ethmoidal region, in the middle fossa, near the end of both lateral sinuses, in the orbits, and in the dura of the vertex. In the trunk chloromatous tissue was found on the internal aspects of all the ribs, the innominate bones and sacrum, and on the external surface of both scapulae. The long bone examined was exempt. All the growths were of an olive-green colour. The liver, spleen, and heart gave a slight iron reaction. Microscopically the growth was a small to a medium-sized round-celled sarcoma. The effect of several reagents on the pigment was tested, but the only one which had a definite solvent or decolorizing action was 0.2 per cent. KOH, which was allowed to act for eighteen hours at 37° C. Special examination was made for the presence of bacteria, but none were detected.

Dr. A. E. GARROD said that cases of sarcomatous growth in the orbit in children associated with sarcoma of the suprarenal capsule presented features similar to those of chloroma. The pigment resembled the lipochromes rather than any derivative of blood pigment.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—At a meeting held on February 12th, Dr. E. SERGEANT, President, in the chair, Dr. F. H. COUTTS, on behalf of the North-Western Branch, presented to the society a framed portrait of Dr. Francis Vacher, who occupied the Presidential chair in 1895. Dr. T. H. C. STEVENSON read a paper upon the *Administration of school medical inspection*, with especial reference to county areas. After describing the routine provision which should be made for the actual inspection, he urged that it was important to interest the teachers in

the work, even though their assistance was not sought. He described the system recently adopted in Somerset for the inspection of the eyes of children whose vision was below $\frac{6}{6}$. A full-time officer had been appointed, who would undertake the ordinary routine inspection in a district, but his services would be available as "school oculist" for the whole county. The gentleman appointed had had considerable experience in ophthalmic work, and this fact was taken into consideration in determining his salary. Eye-testing centres were being established in different parts of the county to which it was hoped the children to be examined would be brought. The oculist, when he examined, would, if necessary, prescribe spectacles, and these were to be supplied at a low rate by the County Council, though in special cases no charge would be made. Dr. Stevenson recommended the provision of a separate weighing machine for each school, and he expressed the opinion that in the long run this would be less costly than paying for the cartage of a machine from one school to another. He considered that there was little or no necessity to duplicate the record cards, the individual normal card was of very little interest and not likely to be referred to. He urged the necessity for proceeding with the tabulation of the results steadily during the year, so that the annual report could be built up in sections and results could be obtained at shorter intervals with comparative ease. He suggested that the best place to keep a record of the infectious illnesses was in the school register. By the addition to it of five narrow columns the teacher could record with very little labour the illnesses which the children were known to have had. Dr. BARWISE said that it was a great advantage to have the children taught to breathe properly. In one district of which he knew, and where the children had been taught the proper method of mouth breathing, there was a noticeable absence of adenoids and of enlarged tonsils. Mr. F. E. FREMANTLE considered that it was important to record the presence of a parent at the inspection in order to know at a subsequent inspection whether directions had been given at first hand. He advocated the employment in each village of a nurse-midwife. Dr. J. T. C. NASH endorsed the latter suggestion, and thought funds might be provided for her support on the provident dispensary principle. Dr. BUTCHER said that he obtained a great deal of assistance from the teachers, especially as regards the clothing and cleanliness of the children, for the latter often came specially prepared for the inspector's visit. Dr. KERR hoped that the inspections would not develop into a mere collection of statistics, for if they did the work would not be worth doing. He considered that the inspectors must have assistance from the teachers, and he suggested the appointment in the infant schools of a person who would be more of a nurse than a teacher, but whose services would be available in the upper schools when the inspector made his periodical visits. Dr. W. BUTLER thought it would be a pity if any doubt were cast as to the necessity for the examinations. He agreed that it was quite unnecessary to duplicate the cards, and feared that the work might be handicapped by the unnecessary clerical work which was being adopted in some districts. The PRESIDENT referred to the insanitary surroundings of many schools, and thought that more attention should be paid to the lessening of the commoner preventable diseases.

CLINICAL SOCIETY OF MANCHESTER.—A meeting was held on February 16th at the Onward Buildings, Deansgate, the PRESIDENT (Dr. J. J. Cox) in the chair. Dr. CHRISTOPHER HEYWOOD opened a discussion on *Whooping-cough*. In the course of his remarks he laid great stress on the value of fresh air in the treatment of this disease, and expressed the opinion that but little reliance was to be placed on drugs. The following gentlemen took part in the discussion: Drs. HUTTON, MUMFORD, MARSDEN, VIVANT BROWN, WILKINSON, LAPAGE, P. R. COOPER, BROADBENT, LARKIN, PRICE-WILLIAMS, SAVATARD, and the PRESIDENT.

The next meeting of the French Congress of Medicine will be held in Paris in 1910, under the presidency of Professor Landouzy. The questions proposed for discussion on the official programme are: (1) Bradycardia. (2) the relations of the liver and spleen in the pathological state, (3) the treatment of symptomatic epilepsies.

Reviews.

PHYSIOLOGICAL PRINCIPLES IN TREATMENT.

AMONG older practitioners of medicine the complaint is often made that the elaborate researches in physiology and physiological chemistry of the last decade are of little service at the bedside. The application to the needs of the patient of the new knowledge acquired in the laboratory is often disappointing, but it is probable that the fault lies for the most part in its misapplication from want of thorough understanding.

In a useful work on *Physiological Principles in Treatment*,¹ Dr. LANGDON BROWN has sought to show to what extent the newer knowledge can be utilized with benefit and in what directions it still needs extension and confirmation.

Organotherapy first claims attention, and the physiological properties and therapeutic values of iodothyron and adrenalin and of extracts of most of the organs of the body are in turn examined. The term "hormone," as indicating a substance normally secreted by a healthy organ and destined to exercise a stimulating effect upon some other organ or system, must now be accepted in medical nomenclature, but among hormones there is none as yet known which exercises so powerful an influence upon the treatment of disease as the normal secretion of the thyroid. The limitations to the use of adrenalin and others are many, and their employment demands caution.

In the rational treatment of gastric disorder there is abundant scope for the application of recent knowledge. The convincing demonstrations of Pawlow have proved the immense influence of the mental processes over gastric secretion, and have opened the way to further discoveries as to the adaptation of secretion to requirement throughout the alimentary canal. The study of gastric and intestinal chemistry proceeds apace, but results must needs be incomplete so long as the psychic element remains unknown.

Purin bodies and their influence upon the healthy organism are closely considered, and the author deals gently with the anti-uric acid enthusiasts on the one hand, and those who attach little importance to it on the other. That the liver, and not the kidney, is the offending organ when the normal output of uric acid is disturbed has been abundantly shown.

The subject of occasional albuminuria is one of constant interest, and much space is devoted to it. Its cause is to be sought for either in defective vasomotor control or in haematogenous irregularity.

The vexed question of the cardiac rhythm is once more enunciated, and the opinions of many observers are quoted, but the practical difficulties of treatment remain as great as ever, since every case of heart disease is complicated in unequal degree by morbid conditions in other organs. An account of the part played by calcium in the body and of the work done by Sir A. E. Wright and his pupils, concludes a book which should be of special interest to those who desire to keep abreast of recent investigations and modern views. Being somewhat overlaid with references to inconclusive observations, it would doubtless gain in simplicity and clearness if the links in the chain of evidence were more clearly defined, and only such observations were quoted as have withstood the test of time or have been accepted by recognized authorities. As a refreshing proof of the vigour of modern energy and ingenuity in research and of its increasing influence upon practical medicine the book deserves a cordial welcome from those for whose enlightenment it has been written.

LOGIC IN MEDICINE.

DR. BIEGANSKI'S book on medical logic,² which Dr. FABIAN has translated into German from the second original edition, contains some suggestive bits of criticism. Protesting

¹ *Physiological Principles in Treatment*. By W. Langdon Brown, M.D., F.R.C.P. London: Baillière, Tindall, and Cox. 1908. (Cr. 8vo, pp. 351, 5s.)

² *Medizinische Logik: Kritik der aertztlichen Erkenntnis*. Von Dr. W. Bieganski. Autorisierte Übersetzung nach der zweiten Original-Auflage, von Dr. A. Fabian. Würzburg: Curt Kabitzsch. 1909. (Roy. 8vo, pp. 238. M. 4.50.)

against the abuse of the so-called scientific hypothesis in medical literature, he writes:

The confusion of hypotheses with facts and the exposition of the facts in the light of explanatory hypothesis is responsible for the rapidity with which our present textbooks and medical treatises become out of date. In science only facts and generalizations which are based upon them are stable; hypotheses change, and often very speedily. If we display our facts in the light of current hypotheses, the overthrow of the latter destroys the entire value of the book. It is for this reason that our modern medical textbooks often lose their entire value within a few years. This would not be the case if strict regard were paid to the difference between what constitutes a *de facto* advance in scientific achievement and what is merely a theoretical surmise; the significance of the work as a record of facts would then retain a permanent value. Take as examples the old textbooks of Stokes, Trousseau, and Griesinger: even at the present day these may be re-read with great profit, owing to their wealthy material of clinical facts.

Reviewers of current medical literature cannot fail to recognize that there is a good deal of truth in this criticism. There is far too much special pleading in favour of some arbitrarily-chosen hypothesis. Writers deliberately set out with the intention of accumulating data in support of some preconceived theory; the facts which are found to be corroboratory are emphasized; those which might be interpreted in an opposite sense are explained away; and the final conclusion is not an objective statement logically deducible from the facts themselves but a personal opinion, leaning upon facts for support but taking root from the author's own mind. The author's ambition is to gain recognition as an authority, to voice his own authority rather than to make the facts speak for themselves. The result is that, on taking a general survey of recent medical literature upon a particular topic, one generally finds a discordant jargon of authorities, each clamouring for his own particular hypothesis. Beneath this confusion it is often difficult to discover a current of steady progress; and, whilst recognizing that there is a legitimate sense in which the working hypothesis is an indispensable guide to scientific research, one cannot help feeling that the weakness of modern research is a tendency to distort the facts in order to support personal opinions. Take better care of the facts and the hypotheses will take care of themselves.

Another interesting chapter in Dr. Bieganski's book is that in which he discusses the use and abuse of medical statistics. Whilst appreciating the important services which have been rendered by statistical methods in confirming leading principles of medical science, he gives some excellent illustrations of the well-known fact that statistical data are often highly misleading. They are frequently accepted as proof of a causal relationship when a closer scrutiny of the basis upon which they are collected would reveal complicating factors which rob mere percentage calculations of the significance they are supposed to possess. About this danger of misapplied statistics there can be no dispute; but perhaps the author does not attach sufficient importance to the work recently done in the application of mathematical methods to the elucidation of general principles from biological and medical statistics. Attention may also be called to Dr. Bieganski's useful analysis of the logical principles involved in establishing a correct diagnosis.

Whilst finding much in this book which we can recommend, it is necessary to add that in some of the chapters—for example, those on clinical observation and the conception of disease—the author indulges in unnecessary verbosity, and is rather commonplace. He wears us with needless platitudes about matters of elementary common sense which are familiar to every medical student.

TEXTBOOKS OF PSYCHIATRY.

In a textbook of mental diseases recently issued under the somewhat comprehensive title of *Mind and its Disorders*,² Dr. W. H. B. STODDART endeavours to provide for the student a succinct account of normal and abnormal mental processes, the attempt being made throughout to relate the mental to the underlying physical or nervous series of events. The work, which contains forty-two chapters and two appendices, is divided into three parts: the first

dealing with normal psychology; the second with the psychology of the insane; and the third with mental diseases, treated methodically and in detail according to their clinical categories. In the first part, on normal psychology, which occupies only the first 97 pages, the author gives brief and practical descriptions of sensation; perception and ideation; affective processes; reflex, automatic, and voluntary action; attention; fatigue; sleep; expression, and so on, as far as is possible, from the physical—that is, from the anatomico-physiological—point of view. Dr. Stoddart excludes, as useless to the practical physician, what he terms in his preface "the transcendental psychology of modern schoolmen," and wisely does not venture into the fascinating, but, from the didactic point of view, unsuitable field of metaphysical speculation. His explanations of mental and neural processes are based throughout on the neurone theory, which, he says, "at the present day meets with almost universal acceptance," with the further support of the theory of the motility of the neurone—that is, the theory of the protrusion and retraction of dendritic 'gemmules.' It is not necessary to enter here into so controversial a question as that of the neurone theory. It is only right to mention, however, that this theory, even though the term "neurone" is in general use, has lost within recent years so many of its former adherents that, though it may be too much to say, with C. Golgi, that it is on its last legs, it is certainly now standing upon its defence. Also the theories of neuronal or gemmular retractility, and inter-neuronal "synaptic resistance," of which Dr. Stoddart makes much use in the subsequent chapters, are of so hypothetical a character—the histological features on which the retractility theory is based being, according to authoritative investigators, artifacts and producible at will by certain methods, notably by the unhappy Golgi method—that a suspended judgement is clearly called for. Passing to Part II, on the psychology of the insane, the author gives very clear and useful descriptions of the disorders of sensation, perception, ideation, the emotions, conduct, and judgement; mainly, and quite rightly, from the point of view of their objective recognition and appreciation by the medical man. In Part III, which takes up much the greater portion of the whole work, after a brief discussion of the causes of insanity and the physical stigmata of degeneration, the author begins his principal task of describing clinical types of insanity. In his classification Dr. Stoddart follows Kraepelin to some extent. Under "intermittent and periodic insanities (maniacal-depressive insanity), the author describes melancholia, mania, anergic stupor, and terminal dementia, and in discussing their pathology he outlines a theory of intraneuronal intoxication, according to which the maniacal phase is due to an irritating toxin, and melancholia to a paralyzing toxin within the cortical nerve cells, the author's explanations being based upon the view of Hughlings Jackson that large proximal-joint slow movements are innervated by large, and small peripheral-joint rapid movements by small cortical cells. Under dementia praecox Kraepelin's three forms are accepted and described with a fourth form, "simple dementia praecox," which is stated to be rare, and characterized by slow dementia supervening upon congenital imbecility. Paranoia, a classification which is steadily gaining wider acceptance in this country, is treated briefly, as are also psychasthenia—limited by the author to irrepressible thoughts, fears, and impulses—neurasthenia, and hysteria. The remaining classification and exposition fall into line with those generally accepted in this country. In the chapter on general paralysis a very good general account of the signs and symptoms of this disease is given, the main physical or neurological features, which have been greatly filled in during recent years, receiving careful consideration. In discussing the etiology of this disease, Dr. Stoddart, who, like the overwhelming majority of writers, considers previous syphilitic infection to be a *sine qua non*, remarks that in China, Japan, and Egypt, in which countries syphilis is rare, general paralysis is of rare occurrence. This statement has been frequently made by other writers, but it would be of value to know how far it rests on unimpeachable evidence. Adequate statistics from China and Japan are wanting, but so far as Egypt is concerned the reports of the Egyptian Government Asylum show that general paralysis accounts for 7 per cent. of the annual

² Lewis's Practical Series. *Mind and its Disorders*. A Textbook for Students and Practitioners. By W. H. B. Stoddart, M.D., F.R.C.P., Assistant Physician to Bethlem Royal Hospital. London: H. K. Lewis, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

admissions, and more than 25 per cent. of the deaths. In writing this book it is clear that Dr. Stoddard has had constantly before him the desirability of viewing symptoms and symptom-complexes with an eye to their neurological significance, and of laying emphasis on the physical signs accompanying the mental disorders treated. Although it is as yet impossible to attach the value of differential criteria to these physical signs as between one psychosis and another, such a mode of looking at them is of the greatest present value, and promises to be of still greater service in the future. The reader will find a great amount of valuable information in the book, even if at times the facts are somewhat baldly stated, and clear and admirable advice upon the treatment of the insane.

Professor WM. WHITE, of Washington, in the foreword to his *Outlines of Psychiatry*,⁴ modestly disclaims for his book any completeness or originality, and states that it is merely intended to afford a helpful guide to his students, so that they may follow his lectures more easily. After a critical perusal of this textbook, however, we cannot but conclude that it is bound to be used with profit by a much wider circle. It is a capital book, well and clearly written; broadly philosophical in its treatment of the nature of mentality; careful and impartial in its examination of the causes of insanity; definite and unambiguous in its descriptions of symptomatological features and clinical types, and thorough in the instructions given as to methods of examination. The author in his classifications follows in the main that of Kraepelin; references and footnotes have been avoided so as not to detract in any way from the continuity of the text, and extended notes of cases are not included for the same reason. The book has a paper cover, but deserves a more durable binding.

We have received the second edition of Professor POTTS'S *Nervous and Mental Diseases*,⁵ a textbook for students and practitioners, whose first edition was reviewed in the BRITISH MEDICAL JOURNAL of March 1st, 1902. The book has received large additions, numerous new illustrations and useful plates have been inserted, and the whole text is excellently illustrated and elucidated by diagrams, plates, and photographs. The chapter on mental diseases has been almost entirely rewritten. The second is a great improvement on the first edition, and forms a very satisfactory textbook for general use, which would be still further improved if the many references to authoritative articles, printed as footnotes, were collected in an authors' index.

A small and handy book, by Professor RÆCKE, tutor and principal medical officer in the Neurological and Psychiatric Clinic at Kiel, on the outlines of diagnosis in psychiatry,⁶ will be found of considerable use to foreign students of German psychiatrial literature, not so much on account of its brief and sharply-drawn pictures of the types of mental disorder, arranged by the author according to the classifications of Binswanger and Siemerling, but because this volume, being intended for students, contains extended definitions of neurological and psychiatrial terms in use in German textbooks, whose exact meaning is rarely given even in technical dictionaries.

Dr. L. PIERCE CLARK, Senior Physician to the Hospital for Nervous Diseases, New York, and Dr. A. R. DIEFFENDORF, Lecturer on Psychiatry at Yale University, the joint authors of a small manual entitled *Neurological and Mental Diagnosis*,⁷ say that the work is designed to aid the student and general practitioner to make thorough and systematic examinations in nervous and mental diseases. The book is composed of two parts, the first on "Methods

of Examination in Neurological Diagnosis," by Dr. Pierce Clark, and the second on "Methods of Examination in Mental Diagnosis," by Dr. Dieffendorf; a glossary and an index. The first part contains succinct and fairly complete directions to the student as to the points to be looked for and the manner of eliciting and recording the same, well illustrated by charts and photographs. Beyond this the author does not go, no attempt being made to describe types of nervous disease. The second part is more complete in plan, the first chapter containing short descriptions of the usual symptoms of mental disorder and the second consisting of clinical descriptions of the several types of mental disorder according to Kraepelin's classification. Each description takes the form of a simple clinical record of a particular case, without any subsequent discussion; differential diagnosis is not touched upon, and in each case only the specific and outstanding features are mentioned.

BACTERIOLOGY.

Dr. EMANUEL VON HIBLER'S researches on the pathogenic anaerobes⁸ form a useful contribution to bacteriology. The present volume deals with fifteen different species, including the bacillus of symptomatic anthrax, varieties of the bacilli of malignant oedema, the tetanus bacillus, and the bacilli associated with epidemics of meat poisoning. In the first part of the book the cultural characters of these various micro-organisms are carefully worked out, and diagnostic points of difference are noted. The remainder of the volume deals with the pathogenicity of the anaerobes and the anatomical and histological characters of the lesions produced. A few points of special interest may be mentioned, as illustrating differences in the virulence of these bacteria for laboratory animals. The bacillus of symptomatic anthrax produces fatal infection in guinea-pigs, rabbits, white mice, white rats, and sparrows, but not in grey rats. In contrast to this organism, the *Bacillus aerogenes capsulatus* rarely produces fatal infection in rabbits, this result being obtained only with young animals inoculated with a large dose of highly virulent culture. The author finds that the *Bacillus enteritidis sporogenes* of Klein may be distinguished from the nearly related bacillus of symptomatic anthrax by the fact that in contrast to the latter it produces progressive and fatal disease in grey rats, but not in white rats and not in sparrows. From an extensive series of microscopic investigations the author arrives at the conclusion that histological examinations of the lesions produced by these varieties of anaerobes do not afford substantial aid to differential diagnosis. The histological picture, in any given infection, is very variable, being largely dependent on the local conditions of the particular piece selected for examination; and even an extended histological study cannot afford justification for more than a general surmise as to the type of infection present; it does not add much to the knowledge which may be derived from the naked-eye appearances alone. In addition to his capacity for original research, Dr. von Hibler has the gift of writing clearly and concisely. His subject-matter is well planned out, and the summaries which he attaches to each chapter enable the reader to grasp the main points without wading through a mass of detail. There is also a valuable collection of plates illustrating the characteristics of pathogenic anaerobes.

Professor HEWLETT has carefully revised his *Manual of Bacteriology*,⁹ and the new edition may be recommended as an excellent book. Two of the best chapters are those on typhoid and plague. They give a good outline of recent research on these subjects, but do not overburden the student with too many minutiae or controversial issues. In this respect the chapter on diphtheria is perhaps rather less successful. Disputed points relating to distinctions between true diphtheria bacilli and various "pseudo" forms are presented fairly and temperately; but these matters are too difficult and complicated to be suitable for brief outline in an elementary textbook. The student to whom bacteriology is a new subject needs something more

⁴ *Outlines of Psychiatry*. By Wm. A. White, M.D., Superintendent of the Government Hospital for the Insane, Washington; Professor of Nervous and Mental Diseases, Georgetown University, Washington, etc. New York: Journal of Nervous and Mental Disease Publishing Co. 1908. (Med. 8vo, pp. 238, 2 dollars.)

⁵ *Nervous and Mental Diseases*. By Charles S. Potts, M.D., Professor of Neurology in the Medical-Chirurgical College of Philadelphia, U.S.A. Second Edition. London: Henry Kimpton. 1908. (Demy 8vo, pp. 570. Illustrations 133, plates ix. 12s. 6d.)

⁶ *Grundriss der psychiatrischen Diagnostik*. (Outlines of Diagnosis in Mental Diseases.) By Professor Dr. Ræcke, with a Preface by Professor Siemerling. Berlin: August Hirschwald. 1908. (Post-8vo, pp. 154. M. 3.)

⁷ *Neurological and Mental Diagnosis: A Manual of Methods*. By L. Pierce Clark, M.A., and A. Ross Dieffendorf, M.D. New York and London: The Macmillan Company. 1908. (Post-8vo, pp. 220. 5s.)

⁸ *Untersuchungen über die pathogenen Anaeroben*. Von Dr. Emanuel von Hibler. Jena: Gustav Fischer. 1908. (Roy. 8vo, pp. 438. 17 plates. M. 25.)

⁹ *A Manual of Bacteriology, Clinical and Applied*. By R. Tanner Hewlett, M.D., F.R.C.P., D.P.H. Third edition. London: J. and A. Churchill. 1908. (Demy 8vo, pp. 650; 24 plates. 10s. 6d.)

simple and categorical to begin with. In the chapter on tuberculosis there is a sentence which is difficult to understand: "It had been known that there are certain differences between the bacilli of human and of bovine tuberculosis, the latter being shorter and thicker, and more readily cultivated than the former." According to most authorities, it is the human and not the bovine bacillus which is "more readily cultivated."

Professor Pozzi-Escot's book on general microbiology¹⁰ is a reproduction of lectures delivered in 1907 before the National School of Agriculture and Veterinary Medicine of Peru. The lectures were intended to be an elementary course, introductory to the more specialized study of industrial or medical bacteriology. The first part of the work gives a popular account of the morphology, physiology, and cultural characters of micro-organisms. Bacterial secretions, toxins, antitoxins, and serumtherapy are also discussed in general outline. The second part of the volume is devoted to the description of the principal groups of microbes, with special reference to their industrial importance in the dairy and in the production of wine, spirits, and beer. There is also a chapter on the bacterial fertilization of the soil. The book is written in a style which will appeal to the general reader who desires a popular and readily assimilated account of what microbiology means. For students whose interests are of a more serious and commercial nature, the utility of the work will depend upon the temperament of the individual. Those who want to plunge at once *in medias res* will prefer a book with fewer preliminary generalizations and more comprehensive details; the student who likes to begin with a gradual initiation into the general point of view will find the author's method acceptable. For the benefit of persons specially interested in the preparation or consumption of alcoholic liquors, it may be mentioned that the author devotes particular attention to the requirements necessary for the production of a delectable flavour in the aromatic constituents of rum.

The *Manual of Bacteriology*, written by Professor WILLIAMS, of Buffalo, and revised by Dr. MEADE BOLTON, of Washington,¹¹ is a rather colourless production, fairly well up to the average, and not calling for much special comment in the way of either praise or blame. Dr. Meade Bolton, who has incorporated a good deal of his own work in the present edition, is well known in America as an expert on the bacteriological examination of water and milk. The chapter on these subjects is the best in the book, and, whilst not sufficiently detailed for the purpose of advanced students, gives the beginner a good general idea of this branch of practical bacteriology. The influence of pasteurization on the bacterial content of milk is a subject of great practical importance, upon which Dr. Bolton's personal experience justifies him in speaking with authority. His general conclusion, with which we agree, is that commercial pasteurization is in need of more rigorous inspection from the public health authorities. In the chapters on the pathogenic bacteria we are glad to see that special attention is paid to clinical diagnosis; the more theoretical aspects of the subject are treated more successfully in some of the students' textbooks by English authors.

Professor JORDAN's *General Bacteriology*,¹² which is based on lectures delivered to students in the University of Chicago, shows that the writer possesses the gift of presenting his subject in an interesting manner. He provides quite as much detail as the elementary student is capable of assimilating, and he makes free use of recent research, but he contrives to avoid the dry-as-dust method, and puts it all in an eminently readable fashion. In addition to the usual routine matter there are chapters on the bacteriology of milk and milk products, the nitrifying organisms, the use of bacteria in tanning, the curing of tobacco, and other industries, and

the bacterial diseases of plants. The last of these chapters is, perhaps, the most interesting. Upon the important question of the bacterial content in milk the writer does not attach sufficient importance to the practical difficulties in the way of reform. Referring to the very low bacterial standard (10,000 bacteria per cubic centimetre) adopted by some of the American Medical Milk Commissions for the production of "certified" milk, he says that "little difficulty has been found" in bringing the bacterial count down to this very low level. That is hardly the case; the number of farmers capable of conforming to this standard is very small, and the output of "certified" milk is extremely limited. Mention is also made of certain American cities which have "established," for the general milk supply, bacterial standards varying in different instances from 500,000 to 100,000. Professor Jordan fails to point out that the mere adoption, as a municipal regulation, of a bacterial standard, is a very different matter from enforcing obedience to such a regulation. Some of the cities which he mentions have found it quite impossible to prevent the sale of milk containing bacteria in excess of the prescribed limit.

In the third edition of *Pathogenic Micro-organisms*¹³ Dr. W. H. PARK, assisted by Dr. ANNA WILLIAMS, has carried out an extensive revision of the text and considerably expanded the size of the volume. In their excellent account of opsonins the authors call attention to a practical difficulty which is sometimes ignored. They find it is generally impossible to have the test of the opsonic power reported within twenty-four hours, and in the treatment of the poor in out-patient practice the interval between taking the sample for diagnosis and performing the vaccination may be much longer; in the meantime an important change may have taken place in the opsonic index. This impossibility of knowing the opsonic power at the moment of inoculation has been found by the authors to constitute a very serious difficulty. There is a useful chapter on the characters and distribution of the bacteria normally present in the intestinal tract. A good feature of the important chapter on the tubercle bacillus is that special attention is given to points of practical importance, such as the presence of tubercle bacilli in the milk of cows which have no other disease but react to tuberculin, and the occurrence of the bacillus in the faeces of cows with internal tuberculosis. The well-informed and thoroughly practical article on the general bacteriology of milk is also deserving of special praise. As we remarked in our review of the second edition (BRITISH MEDICAL JOURNAL, May 26th, 1906, p. 1225), the volume is well above the average of the ordinary student's textbook, and may be warmly recommended.

Dr. M. V. BALL's *Essentials of Bacteriology*,¹⁴ which has now arrived at its sixth edition, may find favour with students who like to acquire their knowledge from books prepared on the *mullum in parvo* principle. The author is particularly successful in packing a large amount of detail into a small space, and may be especially commended for introducing a chapter on various bacteria which are pathogenic for animals but not for man; the interest and importance of these micro-organisms is often overlooked by the average medical student. Speaking of typhoid carriers, Dr. Ball says: "Some individuals retain a culture of the bacilli in the gall bladder for years, and manufacture, or at least expel, true virulent bacilli through the faeces continually." The word "continually" is a little too strong, and may be misleading; the discharges of bacilli may be intermittent, and it may be necessary to examine the stools several times before obtaining a positive result. The methods of cultivating the tubercle bacillus are not described very carefully. It is said that glycerin agar is a much better medium than blood serum, and that it "is now almost exclusively used." On the contrary, blood serum is still used extensively, particularly for raising primary cultures; and most observers find that for this purpose it is a better medium than glycerin agar.

¹⁰ *Leçons élémentaires de Microbiologie Générale*. Par M. Emm. Pozzi-Escot. Paris: Jules Roussel. 1909. (Med. 8vo, pp. 536, figs. 106. Fr. 9.)

¹¹ *A Manual of Bacteriology*. By Herbert Hugh Williams, M.D., revised by Dr. Meade Bolton, M.D. Fifth edition, revised and enlarged. London: Rebmam, Limited. 1908. (Demy 8vo, pp. 460, 113 illustrations. 9s.)

¹² *A Textbook of General Bacteriology*. By Edwin O. Jordan, Ph.D. Philadelphia and London: W. B. Saunders Co. 1908. (Medium 8vo, pp. 557, 163 illustrations. 15s.)

¹³ *Pathogenic Micro-organisms including Bacteria and Protozoa*. By William Hallowell Park, M.D., assisted by Anna W. Williams, M.D. Third edition. London: Henry Kimpton's and Glasgow: Alexander Stenhouse. 1908. (Roy. 8vo, pp. 650; 176 engravings, 5 plates. 18s.)

¹⁴ *Saunders's Question-Compends, No. 20. Essentials of Bacteriology*. By M. V. Ball, M.D. Sixth edition. Philadelphia and London: W. B. Saunders Co. 1908. (Crown 8vo, pp. 390; 155 illustrations. 4s.)

Again, the student is told that "bouillon containing 4 per cent. glycerin is a very good nurture ground"; but he is not informed that, unlike most bacteria, the tubercle bacillus forms a pellicle on the surface instead of growing in the substance of the broth. Whilst admitting that Dr. Ball's book may serve a useful purpose, we think he is claiming too much for it when he says "it aims to contain the essentials of larger works."

The small book on simple aids to the performance of bacteriological investigations, by Drs. ANEL and FICKER,¹² may be found useful by medical practitioners who desire to equip a room for the purpose of making their own bacteriological diagnoses. The authors enter minutely into the practical details of laboratory furniture, the sterilization of apparatus, the preparation of culture media, and other matters upon which the beginner requires careful guidance. The advice is thoroughly sound, and those who cannot afford elaborate or costly equipment will appreciate the practical hints as to various ways in which expense may be saved.

NOTES ON BOOKS.

THE sixty-second volume of *Guy's Hospital Reports*,¹³ that for 1908, is edited by Mr. F. J. STEWARD and Dr. HERBERT FRENCH. It is an extremely valuable number; a few of the papers, all of which are interesting, have already appeared in other publications of more or less ephemeral form, but doubtless *Guy's* men will be pleased to have even these in an easily accessible position in the report of their hospital. Among the more valuable of the contributions appearing for the first time are one on gastro-enterostomy in gastric ulceration by Dr. H. C. Cameron (being part of a thesis for the M.D. degree of the University of Cambridge); one on myasthenia gravis, by Dr. A. S. Morton Palmer (also a Cambridge thesis), which includes a valuable abstract of 124 recorded cases; one on peritoneal adhesions in a series of 50 consecutive post-mortem examinations by Mr. W. M. Mollison and Dr. H. C. Cameron; and one on arterial blood pressure in health and disease by Dr. H. C. Mann. Besides these there is a learned paper by Mr. Richard Assheton on the blastocyst of *Capra*, with some remarks upon the homology of the germinal layers of mammals. The volume, especially as representing the clinical work of the younger men, is highly creditable to the school.

There is nothing exceptionally good in the fourth volume of the eighteenth series of *International Clinics* for 1908.¹⁴ Having said this, it may appear invidious to mention what appear to be the better of its twenty-seven short papers, but perhaps it would seem more so to mention the less good. Among those which promise to have permanent value are one on acute dilatation of the stomach, by Dr. A. G. Nicholls; one on splanchnoptosis, by Dr. T. R. Brown; one on paronychia lateralis, by Dr. C. G. Cumston; and one on the serum treatment of epidemic cerebro-spinal meningitis, by Dr. C. H. Dunn. An unusually large proportion of the papers, twenty-three out of twenty-seven, are by American authors.

The publication of a new edition of PENZOLDT and STINZING's handbook of therapeutics¹⁵ has been commenced, and the first fasciculus of the first volume reached us on February 26th. The first edition appeared fourteen years ago, and as a second and third have already been disposed of, the work, in spite of its large size and costliness, has clearly met the needs of the profession in Germany, and has become well known in other countries. The new edition will be enlarged by the inclusion of articles on surgical treatment, and on gynaecology and obstetrics. The list of contributors has been revised, and many new recruits have been enlisted. The first fasciculus of the new edition, which can be purchased as a specimen for 1 mark, contains an article on general prophylaxis of infectious diseases, by Professor Gärtner

¹² *Einfache Hilfsmittel zur Ausführung bakteriologischer Untersuchungen*. Von Dr. R. Anel und Dr. M. Ficker. 2. Auflage. Würzburg: Curt Kabitzsch. 1909. (Fcap. 8vo, pp. 57, M. 1.20.)

¹³ *Guy's Hospital Reports*. Edited by F. J. Steward, M.S., and H. French, M.D. Vol. lxi (vol. xlvii of third series). London: J. and A. Churchill. 1908. (Demy 8vo, pp. 238.)

¹⁴ *International Clinics*. Edited by W. P. Longcope, M.D. Vol. iv. Eighteenth Series. 1908. Philadelphia and London: J. B. Lippincott Co. 1908. (Roy. 8vo, pp. 318.)

¹⁵ Penzoldt and Stinzling's *Handbuch der gesamten Therapie*. Fasciculus I. 4th edition, in 25 parts, forming 7 volumes. Jena: G. Fischer. 1909. (Sup. roy. 8vo, pp. 80. M. 1.) The price of the complete work is M.100 in paper covers, or M.117.50 bound. The price of each fasciculus except the first is M.4.50.

of Jena, who was the author of the article on the same subject in the first edition.

The publication of the large work on the diet and dietetic treatment of children, edited by Professor AD. CZERNY and Professor A. KELLER,¹⁶ is proceeding in a most leisurely fashion. In December, 1907, we announced the publication of the first four parts, containing together some 320 pages; we have since received the fifth, sixth, and seventh parts, the last so recently as February 8th, 1909.

¹⁶ *Des Kindes Ernährung, Ernährungsstörungen und Ernährungs-therapie*. Von Professoren Ad. Czerny, of Breslau, and A. Keller, of Berlin. Abt. 5, 6, 1 and 2, Hefte, 1907, Leipzig and Wien: F. Deuticke. 1904-06 and 1909. (Sup. roy. 8vo, pp. 481-699 and 1-256. M.4.50, Abt. 7, M.3.60.)

MEDICINAL AND DIETETIC PREPARATIONS.

Extract of Malt.

OUR attention has been called to an extract of malt sold under the registered name of *Dia Malt*. It appears to be a pure extract of malt, free from any foreign ingredient, and of an unusually high diastasic power, inasmuch as the sample examined was found to digest practically fourteen times its own weight of starch in half an hour. The proportion of proteids was 5.8 per cent., which is higher than in many other extracts; it is a palatable preparation, and as it is also very active it is likely to be of use in the treatment of conditions for which malt extract is indicated. It is manufactured by the British Dia Malt Company, 11 and 13, Southwark Street, London, S.E., whose works are at Sawbridgeworth, Hertfordshire. The malting is carried out by an improved principle under an Austrian patent. One of the features of the method is that the malting is done in receivers and not on the floor. The barley, after undergoing a preliminary cleansing, is dried at about 110° F.; it is then steeped in receivers each having a capacity of 100 qrs., or 400 cwt., water is injected from beneath, and the grain is thoroughly cleansed by stirring in these tanks, where it remains from sixty-five to seventy-two hours. The water is then run off and the contents introduced into six large drums, which revolve slowly on a horizontal axis. These drums, known as pneumatic germinators, replace the older method of allowing the grain to germinate on flat floors where it was turned over by hand shovels. Each pneumatic germinator holds 50 qrs., or 200 cwt., and is traversed by a series of perforated tubes; from these tubes moderately cold air is forced into the grain, and in this way the temperature of the process of germination can be accurately controlled and the risk of contamination by mould obviated. The germinated grain is then malted, and the malt ground by roller mills; after mashing in ordinary mash tubs the liquid is drawn off into a receiving chamber and concentrated. The wort pans are made of tinned copper and have rounded corners, every attention being given to cleanliness.

MEDICAL AND SURGICAL APPLIANCES.

Cotton-wool Receptacle for Aurists and Rhinologists.

DR. L. HEMINGTON PEGLER (London) sends a description of a wool-holder made for him by the Holborn Surgical Instrument Company. A removable dome-shaped cover of bright metal encloses the wool by catching on to flat, heavy base of the same material. On one side of the cover are three fenestrations, through which the requisite

pledget can be detached by forceps, the weight of the receptacle keeping it quite firm. The wool is protected when not in use by a movable plate of metal, operated by a small button, and adjusted by a screw at the summit, which plate slides over the apertures, and also serves to alter their shape and dimensions if desired. The holder is best charged through the apertures, longish masses, about the

width of three fingers, being selected from a sheet of long fibre absorbent wool. The shape of the apertures can be ordered to take other forms than the figure shows—for example, parallel slits, inverted triangles, two triangles base to base separated by a cross-bar, or, better still, all of these in one cover. The figure is one-third the size of my own holder, but I have a larger one on my table at the hospital. The whole contrivance is sterilizable.

THE ROYAL COLLEGES AND THE UNIVERSITY OF LONDON.

The Royal College of Physicians of London and the Royal College of Surgeons of England appointed some time ago delegates to consider and propound a scheme for establishing a system of conjoint examinations in accordance with Statute 123 of the University. The delegates were:

Sir R. Douglas Powell, Bart., K.C.V.O., Chairman.	
Dr. Norman Moore.	Dr. H. A. Cayley.
Dr. Edward Liveing.	Mr. Henry Morris, P.R.C.S.
Dr. Frederick Taylor.	Mr. A. Pearce Gould.
Sir William Allchin, M.D.	Mr. H. T. Butlin.
Sir W. Watson Cheyne, Bart., C.B.	Mr. R. J. Godlee.
	Mr. H. H. Clutton.

The report of the delegates dated December 3rd, 1908, was approved and adopted by the Council of the Royal College of Surgeons on December 15th, 1908, and by the Royal College of Physicians on December 17th, 1908. The scheme proposed in this report was communicated to the University of London in a letter addressed to the Vice-Chancellor by the presidents of the two colleges on January 22nd, 1909, asking him to bring the subject before the Senate and expressing the hope that the Senate would see its way to appoint representatives to meet the delegates of the two colleges and discuss the proposals outlined in the report.

REPORT.

The delegates appointed by the Royal Colleges

To consider and draft a scheme which, if approved by the Royal Colleges, shall be submitted to the Senate of the University of London, with the object of establishing a system of Conjoint Examinations.

Beg to report as follows:

Taking into consideration the provisions of Statute 123 of the University of London, the existing conditions of medical education in the metropolis and the undoubted demand for a Degree in Medicine which shall be more accessible to the average London medical student, and assuming the existence of a general desire on the part of the University, the Royal Colleges, and the medical schools of London to unite in a concerted effort to provide such a degree, the delegates are of opinion that there should be little difficulty in arriving at an equitable and advantageous solution of the problem.

Statute 123 of the University of London is as follows:

The Senate may make arrangements with the Royal College of Physicians of London and the Royal College of Surgeons of England, or either of them, to conduct jointly with the Senate examinations in such portions of the subjects included in the course of study for a medical degree as may be agreed upon between the Senate and those colleges, or either of them, and may also make similar arrangements with other corporations and institutions holding professional examinations in subjects included in other courses of study.

At the present time, of the male students who obtain the M.B. or M.D. degree of the London University, 84 per cent. take the diplomas of the Royal Colleges, and of the graduates in medicine of the University of Cambridge 71 per cent. take the diplomas. Of the total number of diplomates of the Royal Colleges 20 per cent. take the degree of the University of London, 16 per cent. the degree of the University of Cambridge, and 15 per cent. the degrees of other universities, English, foreign, or Colonial. It is thus shown that, roughly, one half of the diplomates of the two colleges are also graduates in medicine.

During the four years 1903-6:

(1) Of Bachelors and Doctors of Medicine in the University of London *Calendar* for 1907-8 there are respectively 365 and 164 male graduates who obtained their degrees during these years. Of such graduates, 311 (85.2 per cent.) and 135 (82.3 per cent.) were at the time, or became subsequently, diplomates of the Royal Colleges. Therefore, of the total male graduates in Medicine—that is, 525—446, or 84.3 per cent., are also diplomates of the Royal Colleges.

(2) Of 253 men who obtained the degree of M.B. of the University of Cambridge, 181, or 71.5 per cent., hold the diplomas of L.R.C.P. and M.R.C.S.

(3) Of 1,704 candidates who obtained the diplomas of L.R.C.P. and M.R.C.S., 885, or 51.9 per cent., are also graduates of or candidates for the degrees in Medicine of the following Universities:

- (a) Cambridge, 274, or 15.1 per cent.
- (b) London, 347, or 20.4 per cent.

- (c) Other English Universities, 119, or 7 per cent.
- (d) Irish and Scottish Universities, 17, or 0.9 per cent.
- (e) Indian and Colonial, 103, or 6 per cent.
- (f) Foreign Universities, 25, or 1.5 per cent.

It is further evident that there is a general desire amongst those who intend to take university degrees or who already possess them to obtain also the diplomas of the Royal Colleges.

It is desirable that in London the system of teaching and examination should be co-ordinated in such a manner as to reduce the number of examinations.

In London the same representatives of medicine and surgery, midwifery, anatomy, physiology, and other subjects, teach for the examinations of the University and of the Royal Colleges. The organization of medical education in London, whether by the University, the Royal College of Physicians, or the Royal College of Surgeons, is largely controlled by the same individuals. Yet for the University and for the Royal Colleges there are separate boards of examiners in all branches of the curriculum, separate examinations involving considerable expense, and a re-examination of the student in the same subjects, frequently within a few months.

The general character of the examinations and the methods of conducting them by the University and by the Royal Colleges are very similar.

The University makes use of the Examination Hall of the Royal Colleges for the Intermediate M.B. examinations, for the *viva voce* examinations in Medicine, Midwifery, Forensic Medicine, Public Health, for the Clinical Examination in Surgery and the examination in Surgical Anatomy and Apparatus for the Final M.B., B.S., as well as for part of the M.S. degree. The rooms of the Royal College of Surgeons and preparations from the Hunterian Museum are placed at the disposal of the University for the pathological part of the Final Examination. The instruments, specimens, and other apparatus of the Conjoint Board are also utilized, and the officials of the Board assist to a considerable extent in the arrangements for some of these University examinations.

In considering such a scheme the delegates have taken as a basis of their deliberations the following principles:

- (a) That the University should retain all its existing rights as to the granting of degrees, but should consent to exercise them as regards pass degrees conjointly with the Royal Colleges so far as those students are concerned who shall have spent not less than four years in study at London medical schools and hospitals and who shall have complied with such conditions as the University and the Royal Colleges may determine.

It is assumed that the University will continue to grant, independently of the Royal Colleges, degrees in Medicine and Surgery, which might be called Honours degrees. The views of those who maintain that the present degrees of the University of London are of an Honours standard would thus be met.

- (b) That the Royal Colleges should retain all their existing rights, to grant diplomas to those who (1) are not eligible under the foregoing conditions; or (2) do not desire to come under such conditions.

It is thus assumed that the Royal Colleges will continue to admit to examination for their diplomas candidates from other universities, home, foreign, and colonial, as well as London medical students who are not students of the London University.

- (c) That the Royal Colleges should be associated with the University in conducting the Preliminary Scientific, Intermediate, and Final Examinations for the Pass Degree (M.B., B.S., M.D.)

This arrangement will secure—

1. That the average London student will be able to obtain the degree of Doctor of Medicine.
2. That medical education in London will become more systematized.
3. That there will be a reduction in the number of examinations to be passed by the student desiring to take a degree and the diplomas.
4. That a larger proportion of students would be encouraged to avail themselves of the great opportunities of clinical study afforded by the hospitals of London.
5. That the University and the Royal Colleges acting together with the same staff and equipment would be able to reduce the expenditure on examinations.

The delegates beg to state that, should the principle of an association between the University and the Royal Colleges be accepted, they are prepared to bring forward a working scheme for carrying the proposal into effect.

In view, however, of the fact that since the appointment of the delegates the Senate of the University has asked for a Royal Commission, the delegates beg to recommend that the Royal Colleges should take steps to secure the representation of their views on the subject of the present reference before any Royal Commission which may be appointed, and should at a fitting time ask the University to appoint delegates to discuss this question with the delegates of the Royal Colleges, so that if possible they may agree upon a joint representation to the Royal Commission.

R. DOUGLAS POWELL.

THE CREMATION SOCIETY OF ENGLAND.

The annual general meeting of members of the Cremation Society of England was held on Wednesday, February 24th, the President, Sir Charles Cameron, M.D., LL.D., being in the chair.

In moving the adoption of the report of the Council and the accounts for 1908, the President recalled the fact that at the last general meeting new rules were sanctioned under which the subscription for life membership of the society was reduced to five guineas. This carried with it the right of cremation, without further fees, in any crematory in Great Britain. This arrangement, he said, had already led to a large increase in the number of life members. The number of cremations in Great Britain in 1908 exceeded that in any previous year, and fell short only by 5 of the round number of 800. The experience of Germany induced him to take a very hopeful view of the present position. There cremation was introduced years before it was practicable in this country, and the cremations performed in Germany up to the present numbered about 20,000. In Germany during the twenty years succeeding 1878, when the pioneer crematory at Gotha was opened, the total number of cremations was only 3,111, giving an average for the period of 155 a year. It was not till 1902 that the number attained the point which had now been reached here. But by that time the movement had taken root, and since then in Germany it had progressed literally by leaps and bounds; the increase on the previous year in 1907 amounted to over 900 cremations, and the figure for 1908 again exceeded that of 1907 by 1,073. As human nature in Germany and in this country was very much the same, and as there were now 13 crematories at work in Great Britain against 16 in Germany, the President saw no reason why the progress of the movement here should not proceed on much the same lines as had been experienced in Germany. Here there was abundant evidence of a widespread and ever-increasing interest in the progress of cremation. During the past year some 500 applications for information of a propagandist character had been received. There had also been some 50 inquiries from municipal or public bodies and individuals at home and abroad regarding the construction and mechanism of crematories, the formation of local societies, points of law, and other technical details. The balance-sheet showed the healthy financial condition of the society. It was not a trading company, but in its future development commercial considerations would have to play a prominent part. He mentioned that an undertaker, who proposed to confine his work exclusively to arrangements for cremations, had started business in London. The President then referred to the security which the precautions required by law before cremation was permitted afforded for the detection of foul play. The investigations of a Parliamentary Committee had disclosed the scandalous laxity and inefficiency of the existing law on death certification. The committee recommended various self-obvious and much-needed reforms, but many years had since elapsed, and the state of the law with regard to earth burial remained as it was. It was very different in the case of cremation. There the requirements of the law were so strict as to render it practically impossible for any suspicious or doubtful case to escape a searching investigation.

After the report and balance sheet had been adopted

and the council and officers re-elected, the election of the following vice-presidents by the council was confirmed by the meeting: The Duke of Bedford, K.G., the Earl of Mayo, P.C., K.P., Right Honourable Sir Walter Foster, P.C., M.P., Right Honourable Robert Farquharson, P.C., Honourable Percy Wyndham, J.P., D.L., Sir G. Anderson Critchett, Bart., F.R.C.S.Ed., C.V.O., and Sir John Tweedy, F.R.C.S.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

The annual general meeting of the Medical Graduates' College and Polyclinic was held at 22, Chancery Street, in London, on March 1st, with Dr. C. THEODORE WILLIAMS in the chair.

Dr. W. H. BAILEY, the new Secretary and Superintendent, read the notice convening the meeting.

The CHAIRMAN, in moving the adoption of the report and balance sheet, said that in regard to the falling off in the number of subscribers it must be remembered that the Polyclinic had to contend with rival institutions. There were the West London Post-Graduate School, the Tottenham and the Greenwich Schools, and in addition, there were some general hospitals, like St. Bartholomew's, where post-graduate courses were conducted. In the matter of lectures, however, the Polyclinic secured the best teaching, not only of London but of the United Kingdom; there had unfortunately been a general feeling during the troublous times of the Polyclinic that the place was not going on and that, therefore, it was no use joining, but he hoped that that impression would be corrected now that it had been agreed to carry on the Polyclinic. After referring to the excellent results of the laboratory work at the Polyclinic the Chairman announced that the institution had been admitted into the London Post-Graduate Association. In consequence of the generous donation from Lord Iveagh of £200, and the munificent offer from Sir Jonathan Hutchinson, the closure of the Polyclinic had been averted. He regretted that 245 of the members and subscribers to the Polyclinic had not returned any answer to the appeal for an increase of their subscription. He then announced that he himself had resigned the office of Chairman of the Council, and that the following resignations had also been received: The Treasurer, Dr. Cautley; the Chairman of the Finance and House Committee, Mr. Ernest Clarke; the Chairman of the Library Lectures Committee, Dr. Leonard Williams; and a large number of members from the Council.

Dr. C. O. HAWTHORNE, in supporting the motion, said that no one failed to recognize the generous and effective help of Sir Jonathan Hutchinson, and the medical profession felt a substantial degree of recognition and gratitude was due to that gentleman. It would not be wise for any of them to go home and think that the Polyclinic was in an absolutely safe position, for it must be remembered that Sir Jonathan Hutchinson had made his offer for two years only; and as a matter of fact, only twelve months would have to pass before the next annual meeting would have to contemplate whether the Polyclinic could be carried on then. He (Dr. Hawthorne) had always held that the wise policy to pursue was to adhere to the 1 guinea subscription; that view did not conflict with the invitation to members to increase their subscription, but it recognized that the chief function of the Polyclinic was to provide opportunities of clinical study to gentlemen who were engaged in practice in the metropolitan districts.

The resolution was put to the meeting and carried.

Dr. Dundas Grant was elected honorary treasurer, and the following gentlemen were elected members of council: Dr. H. Campbell, Dr. G. C. Cathcart, Mr. H. L. Eason, Dr. R. A. Gibbons, Dr. T. N. Kelynak, Mr. Cecil H. Leaf, Dr. James Mackenzie, Mr. Lockhart Mummery, Mr. Charles Ryall, Mr. Thomson Walker, and Mr. G. B. Mower White.

MR. FRANK MADDEN, F.R.C.S., Professor of Surgery at the University of Cairo, has had the honour of receiving from His Highness the Khedive the decoration of the Third Class of the Imperial Order of the Medjidieh on account of services rendered to His Highness's Government. Mr. Madden received his medical education in Melbourne and at St. Mary's Hospital, London. He has been ten years in Cairo.

THE

THERAPEUTIC APPLICATIONS
OF RADIUM:

METHODS AND RESULTS.

SOME OBSERVATIONS ON THE METHODS
AND RESULTS OF RADIUM TREATMENT
IN ENGLAND.

By JAMES MACKENZIE DAVIDSON, M.B., C.M.,

MEDICAL OFFICER IN CHARGE OF X-RAY DEPARTMENT, ROYAL LONDON
OPHTHALMIC HOSPITAL, MOORFIELDS; AND CONSULTING MEDICAL
OFFICER TO X-RAY DEPARTMENT, CHARING CROSS HOSPITAL.

PUBLIC interest in the therapeutic use of radium having been recently revived in this country in a rather sensational manner, it is not altogether a matter for surprise that many rather confused ideas on the subject have become prevalent. It may therefore prove of some service to give a short account of personal experience in the use of radium during the past six years.

As soon as the physical properties of radium became known, it was obvious, in the light of our previous experience of the beneficial effect of x rays and of the ultra violet light (Finsen method) in the treatment of various skin diseases, that this new substance would prove to be of some service in medicine. Indeed, seeing that radium gave forth x rays of extreme penetrability—the gamma rays—in addition to its alpha and beta rays—it seemed likely enough, *a priori*, that it might exceed the results produced by either the x rays or the Finsen method. And such, in fact, has proved to be the case.

Having been fortunate enough to secure some radium bromide of good quality early in 1903, I tried it in a case of severe rodent ulcer, which had resisted x -ray and other treatment, and had been sent to me at Charing Cross Hospital, from the skin department, for further treatment with the x rays. I used two sealed glass tubes, each containing 5 mg. of pure radium bromide, and applied them tentatively on the upper border of the ulcer which was encroaching on the lower right eyelid.¹ After five applications the ulcer, which was 1 in. in length and $\frac{3}{4}$ in. broad, was completely healed. There has never been any recurrence, and at the present time the patient is perfectly well.

This case, at Charing Cross Hospital, in May, 1903, is the first recorded in this country in which radium bromide was applied as a remedy. Since then I have treated a variety of cases in a similar manner, with equally astonishing success.²

As an impression appears to prevail that all the pioneer therapeutic work with radium has been done on the Continent, I should like to point out here that I am by no means the only medical man in this country to obtain very satisfactory results from its application at least two years before the Paris Radium Institute was founded. For example, the late Mr. J. T. P. Hartigan exhibited several successful cases before the Dermatological Society in January, 1904. In the same month Dr. Gerald Sichel reported a cure of rodent ulcer by radium.³ Two months later the BRITISH MEDICAL JOURNAL reported that radium was then being used in the treatment of cancer at the Middlesex Hospital, the Cancer Hospital in the Fulham Road, and other metropolitan hospitals. In April Dr. Colin Campbell reported the cure of 2 cases of tuberculous ulcerations, and Dr. A. J. B. Hammond the cure of yet another case of rodent ulcer by radium. In June, Dr. C. M. O'Brien exhibited to the Royal Academy of Medicine in Dublin two cases of lupus, one of which was greatly improved and the other completely cured by radium bromide. I might mention many more cases did time and space permit, but it must suffice to notice that between that date and the present time several British medical men have reported a number of cures of rodent ulcer, of naevus, and of hairy mole. It should also be put on record that in 1903 the

Royal Ophthalmic Hospital (Moorfields) was presented, by a patient of the present writer, with two tubes of radium bromide of medium quality, by the use of which some excellent results have since been obtained. Radium emanations have been injected hypodermically into patients suffering from malignant diseases, and even radium bromide itself, in solution, has been so injected by the present writer, without however, any definite beneficial effect.

In this connexion I may mention that in cases of carcinoma in which there occurred very small discrete nodules of this disease, and which therefore offered an opportunity of testing the effect of a small amount of radium, I placed radium in a glass tube directly in contact with these nodules; but even after being applied for varying periods, long enough to produce destructive effects, there was no destruction of the cancer cells. Consequently these must be immensely more resistant to the beta and gamma rays than are those of rodent ulcer and epithelioma.

A few words must be said as to the method I have adopted. The application of radium bromide in sealed glass tubes has the advantages that it completely preserves the radium salt from loss by moisture (a matter of the utmost importance in the present scarcity of radium) and that the glass filters out many of those rays which are most easily absorbed, which are therefore most dangerous to the surrounding tissues and which may lead to burning and sloughing. Moreover, as the radium preserved in this way is in a state of radio-active equilibrium, the dosage necessary is merely a matter of time—the length of application in any particular case being of course determined by experience. The range of action of the radium at the bottom of the tube can be seen by its effect on a photographic plate, or, in the dark, when held in contact with a sulphide of zinc screen, or with willemite. The area of action is much wider than might be imagined. One application to a small rodent ulcer is sometimes enough to effect a permanent cure. But in the case of a comparatively large surface the tube must be moved from point to point, which of course takes time, and is a somewhat tedious process.

As this method has recently been severely criticized in this country, it may be worth while pointing out, first, why this particular method was adopted: and, secondly, what it has been able to effect. As to the first point, it is no exaggeration to say that the glass tube method was practically forced upon early workers with radium in this country, on account of the necessity of avoiding the risk of losing so costly and precious a material, seeing that, if lost, it could probably not be replaced. At any rate, it was not from choice, but from necessity, that this method was adopted by me. I was quite familiar enough with the physical properties of radium to realize fully the advantages that would result if it could be spread over a large surface, with some covering material to hold it, which, while allowing free exit to all the radiations, would preserve the precious material intact. But how to do this is by no means so easy as it may appear to those who have never tried it, and few medical men in this country would feel disposed to lose £500 worth in the attempt. It is interesting to know that this problem of the safe spreading of radium has apparently been solved in Paris, where there exists an institute with over £10,000 worth of radium to experiment with.

But before saying anything about the admittedly great advantages of the spread method, it may be some consolation to those who possess radium bromide in sealed glass tubes, and who may not be able to get it safely spread, if I point out that, in this form, it is not so entirely worthless as they might have been led to believe. Applied in this way by me, it has undoubtedly cured extensive rodent ulcer that had resisted all other treatment; it has cured small epitheliomata; it has cured "spring catarrh" of the eyes (which had resisted other treatment for two years); it has cured recurring erosion of the cornea (Arlt) of one year's duration, and tuberculosis verrucosa.

In addition to these, there is one result obtained by this method of treatment which seems worthy of special record. In common with other early workers with x rays, my right hand has suffered from the ill effects of undue exposure, and some time ago an abrasion, produced by a slight injury, presented a rather alarming appearance.

¹ BRITISH MEDICAL JOURNAL, January 23rd, 1904, pp. 181-2.² BRITISH MEDICAL JOURNAL, January 23rd, 1904, pp. 181-2, and Transactions of the Ophthalmological Society, vol. xvi.³ Vide BRITISH MEDICAL JOURNAL, January 23rd, 1904, pp. 182-3.

A hard, thickened border, with a black crust, appeared, and when this had persisted for over two years it became somewhat disquieting. It occurred to me to try my glass tube of radium upon it, and the result has been that one application of a tube, containing about 29 mg. of radium bromide, for fifteen minutes led to its complete disappearance. The same favourable result has followed upon other similar applications. This experience may, I hope, be of use to those who have suffered from their work with x rays. At any rate, it will be important to know if they also find radium bromide act as a cure.

In the light of practical experience thus obtained I may perhaps say a few words concerning the method of treating skin diseases by means of spread radium in the *Laboratoire Biologique de Radium* at Paris. There are two great advantages in this method. First, it enables all the radium radiations to come into effective action on the surface to which they are applied. So that all the alpha, beta, and gamma rays may be used, or by the interposition of certain screens all the alpha rays may be cut off, and, if necessary, the beta rays also. A sheet of paper suffices to cut off all the alpha rays; the beta rays may be cut off by aluminium or leaden screens of varying thickness. The quantity and quality of the rays best suited to cure any particular disease can only be arrived at by trial, and much valuable work in this direction has been done at the Paris Institute.⁴ But it is a regrettable fact that the varnish used to protect the radium and the method of spreading it are kept secrets.

In all successful cases the remarkable effect is shown that by properly timed exposures the abnormal cells invading the human body are gradually destroyed and absorbed, while none of the normal healthy cells are destroyed. Such being the fact, two questions naturally arise: (1) Which of the radiations produce the beneficial results? and (2) What are the abnormal cells which are more resistant to the radiations than the normal body cells? These questions open up an enormous field for careful investigation.

It must be remembered that radium is not the only radio-active body giving off alpha, beta, and gamma rays. There are other substances which do so, such as thorium and actinium, and doubtless others which remain to be discovered. Another point which should not be forgotten, for it is one of great practical importance, is the fact that radium itself does not directly produce all the rays. It first produces what has been called an *emanation*. The disintegration of this emanation causes it to give out the three types of rays, and the therapeutic action of radium depends mainly on the amount of emanation which it contains. If this store of emanation is driven off by dissolving the radium in water, it proves to be a gas, which, when collected, gives out the same amount of alpha, beta, and gamma rays that it did when unseparated from the radium. But, while the de-emanated radium goes on slowly producing and storing up more emanation until in about one month's time it has regained its maximum strength, the emanation which has been thus separated from its parent, goes on decaying, losing about half its strength in about four days, and becoming in about sixteen days almost powerless. The important practical point to be noted is that the effect of the rays from a given quantity of separated emanation is as powerful as when it was contained in the radium, and that, consequently, it is possible to send a tube of the emanation to be used in the treatment of a case at a considerable distance without any risk of losing the precious radium itself in course of transport.

Should any extensive supply of radium become available, results may be obtained such as we little dream of to-day. At the same time, the hopes we entertain of its further utility must not lead us to outrun discretion by leading unscientific people to think that in this quite-sufficiently-amazing substance we have found a panacea for all the ills that flesh is heir to.

His Majesty King Edward (always thoughtful in promoting the best interests of mankind) has recently initiated a Radium Institute in England, and I trust that this institution, with its ample resources, will do excellent work in this wide field of research.

THE METHODS OF FILTRATION AND "CROSSED-FIRE."

[FROM OUR PARIS CORRESPONDENT.]

ONE of the most striking points in the use of radium is the multiplicity of action that can be obtained by the use of one or two apparatus—for example, with a rectangular apparatus 3 cm. by 4 cm., containing 12 cg. of radium (3 cg. pure salt), with A 500,000, therapeutic effects can be directed:

1. To the surface alone, causing violent irritation and destruction.
2. To the surface of the tissues alone without any irritation or destruction.
3. To a depth without irritating the surface or destruction.
4. To a depth, destroying the surface as well as the deeper parts.
5. To the surface and at a depth simultaneously with a strength about the same throughout, and without any destruction of tissue.

Therapeutic results are obtainable from each of these five modes of applications, and each has its utility. If the apparatus is employed without screens, actions 1, 2, or 5 are obtained according to the method used.

If screens are interposed between the apparatus and the tissues, then intermediary actions 3, 4, or 5 are obtained. Amongst these various methods, the most striking are those which produce results at a depth without any alteration of the tissues at the surface—for example, in actions 3 and 5.

The most interesting of the several techniques which give this result are the filtration through thick screens combined with the method named by Drs. Wickham and Degrais "Crossed-Fire."

Dr. Wickham, in 1905, began to filter the radium rays through compressed cotton-wool and then through aluminium, and with Dr. Degrais through lead and rubber. The x rays can only traverse thin sheets of aluminium, and are quickly stopped by denser metallic sheets—for example, of lead. The penetrating power of the hard beta and the gamma rays of radium is so great that they can act through a thickness of 3 or 4 mm. of lead. In January, 1907, Drs. Wickham and Degrais first employed the sheets of lead and rubber used in x -ray work to protect the operator and the healthy tissues. The case was an inoperable glaucoma, the two apparatuses being applied on the forehead and the temple, a sheet of lead and rubber of 1.28 mm. thickness being interposed between the apparatus and the skin. Thus, all the rays which acted on the surface were stopped, and those of great penetrating power had to traverse the bone to reach the eye. In this case the treatment had little effect on the disease, but was of interest historically, as it led the way to other applications, for soon after Drs. Wickham and Degrais treated in the same way a case of cancer of the breast most successfully; the breast was cured, and during the whole treatment there never appeared any irritation of the skin surface.

Filtration thus has the advantage of allowing the passage of rays which act at a depth without any alteration at the skin surface, but it has the disadvantage of diminishing the sum total of the rays in such proportions that, to obtain a therapeutic result, the applications must be of extremely long duration—from 50 to 200 hours, according to the results to be obtained. By this length of the periods of application the small quantity of very penetrating rays, produce in the end a very intense action. For the application of radium for these long periods the apparatus must be convenient, but once the apparatus has been sheathed in its lead casings and it has been ascertained that the radio-activity which passes does not exceed 4,000 to 5,000, then the apparatus can be left in contact with the skin for several days or nights in succession without the slightest inconvenience to the patient. These very penetrating rays (*surpénétrant*) consist of the hard beta and gamma rays, the lead filter having absorbed the alpha, soft beta, and medium beta rays. Dr. Dominici, the collaborator of Drs. Wickham and Degrais, gave the name "ultra-penetrating" to the

⁴ For full details see paper by Louis Wickham et Degrais, "Traitement des Angiomes (Tumeurs Vasculaires et Taches de Vin) par le Radium," Paris, 1908.

gamma rays, but has since recognized that a large number of the beta rays do also pass the filter.

The drawback due to the feeble quantity of these rays which pass the filter has been overcome by Drs. Wickham and Degrais by the adoption of the method of "crossed-fire," the action of the rays resembling a bombardment by batteries at two points facing each other. Thus if two apparatus are placed facing each other on opposite sides of a tumour, these very penetrating rays traverse the tumour in both directions and cross in the centre. The cells are thus doubly acted on, and are modified much more rapidly. If two powerful apparatus of activity 2,000 to 4,000, enveloped each in a sheath of lead 1 mm. thick, are applied, they can be fixed, without any risk or irritation, to the skin surface, and left *in situ* during five or six nights running; but the cells at a depth are acted on by an intense force, which Drs. Wickham and Degrais found was more than double the force of each apparatus taken alone, the "crossed-fire" having increased the intensity of the effect produced on the cells placed deeply, because during a short period the cell is attacked by the double force.

Conclusions.

1. The system of filtration devised by Dr. Wickham permits the separate action of the very penetrating rays.

2. The feeble quantity of these rays is compensated:

(a) By the long durations of the applications which are facilitated by the ease of the applications.

(b) By the method of "crossed-fire," which diminishes the duration of the necessary applications, because they considerably increase the action of the very penetrating rays.

3. These methods allow of action at a great depth without any alteration of the surface.

4. All affections which spread at a depth, as cancer, cheloids, angiomatous tumours, even if situated below the skin, can all be treated by these methods.

5. These results render radium superior to the x rays, which cannot act, either at such a depth or during such a lengthy period, or as conveniently, or with such security for the integrity of the skin surface.

Clinical Cases.

The following clinical observations illustrate the method of filtration combined with the "crossed-fire."

I. Case of an enormous cancerous tumour of the parotid, presented to the Société Médicale des Hôpitaux November 6th, 1908. The patient came to Drs. Wickham and Degrais on August 18th, 1908, the tumour making a projection of 4.8 to 5 cm. at different points, and spreading in width for a space of 9.5 cm. from the ear to the inner quarter of the cheek; its vertical measure was 11 cm. The surface was mammillated, and it was completely covered by the skin except at its most prominent point, where recent ulceration was started. The skin was red, violet in places, and stretched; it was impossible to fold it, and it looked like the skin of an orange; a rich venous plexus ran over the surface. The voluminous mass had raised the cutaneous covering, and presented at its margin a very distinctly accentuated demarcation; there was scarcely any transition between the diseased and healthy tissues. The tumour was firmly adherent to the subjacent tissues, and it was hard, like plaster. The tumour, in spite of its size (it enclosed the region of the facial nerve), and in spite of the extreme tension of the tissues, did not cause any pain; there was some glandular enlargement behind and below the angle of the lower jaw. Dr. Duprey, of Châteauneuf-Chinon, wrote that the patient, whom he had known for twenty years, had had a tumour of the parotid, which he considered a fibroma, for fifteen years, and that eighteen months previously it had suddenly developed rapidly, and taken on a malignant character. Microscopic examination by Dr. Dominici showed it to be a lobulated epithelioma, with cells with budding nuclei; numerous cells showed ordinary and multipolar karyokinesis; there was little production of horny substance. Treatment was begun at once, based on the principle of the "crossed-fire," by introduction of tubes of radium into the interior of the tumour; apparatus were also applied externally, so that the crossing of the rays was tenfold. By these methods, and by changing the position of the apparatus, Drs. Wickham and Degrais were able, while respecting the surface, to act with extreme force in the depth of the tumour. After eleven weeks' treatment the tumour had retrogressed so much that its thickness was only 4.5 cm., its vertical and transverse diameters being also much reduced. The tumour became quite mobile on the subjacent tissues and was no longer hard; the lymphatic glands, which had also been treated, showed no more threatening points. At the present time the patient is cured.

II. Cancer of the Breast.—Three cases treated by the same process. The apparatus were covered with 2 mm. of lead and placed on the breast to be treated to the number of four, two by two on opposite sides; they were left in place twelve hours each time on alternate nights. The activity of each apparatus was 2,000 to 3,000. Their size varied from 12 to 20 sq. cm. of surface. They were slightly changed in position at each application, so that the skin surface ran no risk. A first series of applications consisted of ten nights. After a month's rest, a fresh series of ten nights; again a month's rest, followed by a third series. From the first month there was great improvement, the supples returned, the tumours were no longer adherent, the regression was progressive. About the fourth month, nothing remained of the cancers.

III. Cancer of the uterus, with invasion of the lymphatic glands. An apparatus was fixed in the vagina against the uterus; four apparatus were placed on the abdominal wall, two to the right and two to the left side. The pains ceased quickly and the tumours retrogressed. The amelioration was evident, and towards the third month by abdominal palpation it was impossible to detect any hardness, and hæmorrhage and the discharge had stopped. The vegetations at the cervix disappeared and the uterus regained its suppleness. The cancer, which had been inoperable and was despaired of, became operable. The patient was operated on and has since remained in good condition.

IV. Carcinomatous tumour in the neck, causing compression of the nerves of neck, severe pains and immobilization of the head. During the first month the treatment caused cessation of the pains, and the head again became mobile. In the third month the patient could turn the head without discomfort, and the tumour, which had been inoperable and despaired of, had diminished by half. The treatment is still being continued, but the result already obtained is very interesting.

THE REPORT OF THE CORONER FOR THE CITY OF LONDON.

The report of Dr. Waldo, Coroner for the City of London, on his work during 1908, which was presented to the Court of Common Council on February 25th, presents several points of interest.

Inquests.

The total number of inquests held was 418, including non-fatal fire inquests. These were distributed as follows: For the City of London, 194 deaths (142 males and 52 females), or 4 more than in the previous year. For the Borough of Southwark, 221 deaths (146 males and 75 females). The Coroner also inquired into other deaths notified to him, but after preliminary inquiries decided that formal public inquests were unnecessary. In the City of London there were 20 such deaths, as against 12 during 1907; and in the Borough of Southwark 64 such deaths, as against 60 during 1907. In 136 cases the Coroner's jury were satisfied that death was due to an ascertained natural cause as against 141 in 1907, while in 279 cases the cause of death could not be described—that is, it was either proved to be not natural, or the evidence was not sufficient to show whether it was natural or otherwise. Of the 279 deaths from other than natural causes 199 are accounted for by accident, as against 212 during 1907. It may be noted that 37 fatalities were due to vehicles, of which 9 in the City and 13 in Southwark were drawn by horses, and 12 in the City and 3 in Southwark were motor drawn.

There was an increase under the class "Suicide," and a decrease under the class of "Children suffocated whilst in bed with their parents or others." Inquests were held on the bodies of 10 infants suffocated whilst in bed with their parents, as against 23 in 1907. During the year there were 29 verdicts of self-destruction while insane, and 10 of self-murder or *felo-de-se*, while in 1907 there were 22 verdicts of self-destruction and 6 of suicide or *felo-de-se*.

Of the deaths attributable to "neglect, exposure or excess," 9 in number, only 5 (2 males and 3 females) were found by the jury to be directly due to disease caused by excessive drinking. In 1907 the number of deaths attributable to that cause was 14. In a considerable number of "natural" and "accidental" deaths, however, there was ground for believing that intemperance was a contributory factor.

Deaths under Anaesthesia.

Dr. Waldo states that a tentative measure in the shape of a proposed General Anaesthetics Bill is now under the consideration of the Privy Council and Home Office, which

bill limits the administration of anaesthetics to registered medical practitioners, and requires that all candidates before presenting themselves for their final medical examination shall have received thorough theoretical and practical instruction in anaesthetics under the supervision and to the complete satisfaction of their respective teachers. He thinks it has been conclusively shown (a) that present available data as to deaths during anaesthesia are so imperfect as to be useless for the purposes of formal investigation, and that it is highly desirable to arrive at satisfactory conclusions regarding all deaths under anaesthesia, both for the safety of the public and for the furtherance of scientific knowledge. At the request of a jury he sent in a rider at the latter end of 1907 to the authorities of a large and important general hospital in South London concerning the death of a young married woman who died under an operation from heart failure due to the administration of an anaesthetic known as chloroform. The rider was to the effect that:

Whilst no blame is attached by the jury to the administrator considering his limited experience, they recommend (1) that in all operation cases of a serious nature anaesthetics should be administered either by a staff anaesthetist or by a resident under his immediate supervision; and (2) that full statistical tables as to anaesthetics should be kept by the hospital authorities.

The receipt of this communication (the Coroner continues) was followed by an inquiry at the hospital in question, and the fact may be noted that, whereas 11 deaths under anaesthetics were reported to him during 1907, only 1 such death from the same hospital was reported during the year under report (1908). He points out, however, that it would be unsafe to draw conclusions from small numbers and from a single year.

The actual figures for past years in this particular institution were as follows:

Year.	Deaths under Anaesthetics.			
1901 half year	2
1902 whole year	7
1903 "	2
1904 "	7
1905 "	2
1906 "	7
1907 "	11
1908 "	1*

* Inquest held January 7th.

With the view of lessening the numbers of what he regarded as unnecessary deaths under anaesthesia, the following recommendations were made by Dr. Waldo:

1. That no general or local anaesthetic shall be administered by any but a duly qualified medical man, except under most exceptional circumstances, which shall be duly reported to some recognized official authority.
2. That full details be reported by the anaesthetist of all administrations of anaesthetics, whether in hospital or in private practice, including date, name and address of patient, of operator and of administrator, nature of operation, the drug used, and other pertinent details.
3. That a register of all administrations of anaesthetics be kept in all medical charities, Poor Law infirmaries, and other public institutions.
4. That, so far as possible, special skilled anaesthetists be appointed to all hospitals and infirmaries, and that resident anaesthetists be provided in the larger institutions.
5. That when the administration of an anaesthetic is entrusted to a junior qualified man he should be supervised by a skilled anaesthetist, except where he can produce a certificate of special skill and experience as an administrator, or where a skilled anaesthetist is not available.
- * 6. That notification be made to the coroner of all deaths occurring at any stage of general anaesthesia by the anaesthetist or by others concerned.
7. That coroners be required to hold a public inquiry into all cases of death during anaesthesia, and that they make a detailed report to the Registrar-General, together with the verdict.
8. That a Royal Commission, with advisory powers, might with advantage be appointed to inquire into the present facts of deaths under anaesthesia, together with the official machinery available for registration.

The Departmental Committee appointed by the Secretary of State to inquire into coroner's law and practice, now sitting, is taking evidence on deaths under anaesthetics.

Poisons and Pharmacy Act.

Another point touched upon by Dr. Waldo is the working of the Pharmacy Act. He says that a new Poisons and Pharmacy Act, which passed during the last session of Parliament, will come into force on April 1st. By this Act restrictions are for the first time placed on the sale of poisonous substances, such as hydrochloric, nitric, and sulphuric acids—a reform often suggested to the Home Office by City juries. He points out, however, that no mention is made of the equally poisonous liquid ammonia or of bichromate of potash, notwithstanding the fact that cases of accidental poisoning by both these substances have been brought to the notice of the Home Secretary by Dr. Waldo, with recommendations from juries that they be made subject to regulation as scheduled poisons. A particularly sad case in point, that of a girl aged 15 years, was investigated by him in 1908. Her death was caused by eating a piece of the salt of bichromate of potassium in the belief that it was a sweetmeat.

Protection of Infant Life.

Dealing with the protection of infant life, the coroner refers to the Children Act, 1908, which will come into force on April 1st, 1909. Amongst other matters, it renders punishable the exposure of a child under the age of 7 years to an inefficiently guarded fire.

The importance of this matter may be at once seen, says Dr. Waldo, when the fact is known that he has held inquests during the past year on 24 children, as against 19 in 1907, under the age of 7 years who were burnt or scalded to death owing, in a large majority of the cases, to the child having been carelessly left alone in a room containing an open fire grate without guard. In a few of these cases the cause of death was due to the child having been left alone with matches lying about.

So far as overlying is concerned, he thinks the Act certainly does not err on the side of severity. The recommendation of the Coroners Bill was that mere suffocation of an infant in bed should be regarded as evidence of neglect, but the Act has made it punishable only when proof is obtained that the parent or guardian was under the influence of drink, evidence of which, so far as he can see, it will be almost impossible to obtain in any court of law.

Identification of Dead Bodies.

Dr. Waldo states that, as regards the better identification of dead bodies, the matter has recently been settled by the determination of the Court of Common Council to instal at the City mortuary an apparatus similar to that in use at Brussels for the preservation of bodies by the agency of formalin.

The fourth Latin-American Congress will be held this year at Rio de Janeiro. In connexion with the Congress there will be an International Hygienic Exhibition, which will be open from August 1st to September 30th. Communications relative to the exhibition should be addressed to the General Secretary, 7, rua Uruguanana, Rio de Janeiro.

DURING the year 1908 the total number of bodies disposed of by cremation in Germany was 4,050 as against 2,977 in 1907, showing an increase of 1,073, or 36 per cent. The figures for the crematories at Bremen, Chemnitz, Coburg, Gotha, Hamburg, Jena, Karlsruhe, Mainz, Mannheim, Offenbach-on-the-Main, Pönsbeck, Stuttgart, and Ulm are all larger than those in the previous year. At Eisenach, Heidelberg, and Heilbronn there was a slight diminution. Among those whose remains were cremated were 1,474 females. The classification according to religious creeds gives some interesting results: Lutheranism stands at the head with 3,236 cases: 299 are described as Roman Catholics, 35 as Old Catholics, 153 as Jews, 72 as "free-religious," 49 as Dissenters, while 9 are described as belonging to other sects. In 197 cases no mention was made of creed. From these figures it appears that while the enormous majority of persons cremated were described as Lutherans, there was a considerable body of Catholics, notwithstanding the prohibition issued, we believe, by Leo the Thirteenth. For some reason, in Germany, as in France, cremation does not seem to appeal to free thinkers. In 2,517 cases, all coming under the head of Lutherans the incineration was accompanied by religious rites.

Medical News.

THE "E. M. I." (Études Médicales Internationales) has arranged this year to visit the medical schools of England, Scotland, and Ireland.

DR. WEIR MITCHELL of Philadelphia, the distinguished neurologist, who has also won fame as a novelist, celebrated his 80th birthday on February 15th.

THE lectures arranged by the National League for Physical Education and Improvement to be given on March 4th and 11th have been unavoidably postponed.

THE Association Générale des Médecins de France will formally celebrate the fiftieth anniversary of its foundation in April. It came into existence on August 30th, 1858.

THE next dinner of the Irish Medical Schools' and Graduates' Association will be held at the Hotel Cecil, London, on Thursday, March 18th; Lord Ashbourne will be the guest of the evening.

THE direction of the Hygiene Exhibition, to be held at Dresden in 1911, has been entrusted to Dr. O. Neustätter, co-editor of the *Gesundheitslehre*, a journal which is largely devoted to the exposure of quacks.

ON Tuesday next at 8 p.m., Dr. A. Harden, F.I.C., of the Lister Institute of Preventive Medicine, will read a paper on the relations to pharmacology of some recent advances in biological chemistry, before the Pharmaceutical Society of Great Britain.

M. MESUREUR, Director of Public Assistance in Paris, has paid English nursing a remarkable compliment by arranging that four French nurses should have a short course of practical training at St. Bartholomew's Hospital.

THE annual conversazione of the West London Post-Graduate College will be held at the hospital on Wednesday, March 24th, at 8.30 p.m. All past and present members of the college are cordially invited, and an invitation will be sent to any medical man applying to the Dean at the hospital.

THE University of Edinburgh will, at the approaching Spring Graduation, confer the honorary degree of LL.D. on Emeritus Professor Alexander Crum Brown, till lately Professor of Chemistry in that University; and on Surgeon-General Sir A. Keogh, K.C.B., Director-General of the Army Medical Service.

ARGYLLS LIMITED, the company which makes the Argyll motor cars, has recently undergone reorganization, and proposes shortly to open a dépôt in London, which will be under the direct control of the management of the works at Alexandria by Glasgow, to which address for all present all communications should be sent.

THE Colonial Office has issued a revised edition of the Memorandum on Medical Appointments in the Colonies, and also of the pamphlet entitled Information for the Use of Candidates for Appointment on the West African Medical Staff. Inquiries should be addressed to the Assistant Private Secretary, Colonial Office, Downing Street, S.W.

AN ophthalmic exhibition will be held on Friday and Saturday, March 12th and 13th, from noon to 10 p.m. each day in the rooms of the Medical Society of London. Its object is to bring under notice the latest models and improvements and a number of optical firms of repute will show apparatus and instruments. Particulars can be obtained on application to Mr. Ernest Schofield, 11, Chandos Street, London, W.

A PROVINCIAL sessional meeting of the Royal Sanitary Institute will be held in the University, Sheffield, on Friday, March 12th, and Saturday, March 13th. On the first day a discussion on medical inspection and its relation to the home life of children will be opened by Dr. Ralph P. Williams, School Medical Officer, Sheffield, and on the following day inspections will be made of the Plenum system of ventilation, new sewage works, and a smoke prevention exhibition.

FOLLOWING out the line of action adopted by the North Northumberland Division of the British Medical Association, the members of the West Penwith Medical Society, Penzance, mainly composed of members of the British Medical Association, passed the following resolution at a meeting held on February 24th: "That this Society unanimously disapproves of midwives engaging to attend cases for whom a medical man has not been engaged to attend, and they desire to point out to all nursing associations in West Penwith that they have unanimously resolved that they will not hold themselves responsible for attendance on such cases."

SIR THOMAS R. FRASER AND DR. JAMES A. GUNN reported recently to the Royal Society the result of experiments made in the Pharmacology Laboratory of the University of Edinburgh on the action of the venom of the South African *Sepeodon haemachates*. Its primary and greatest effect was found to be upon the respiration. In mammals death was found to be respiratory failure produced by paralysis of the respiratory centre, the excitability of the phrenic nerve ends being practically unimpaired. The venom also had a marked enfeebling action on the brain and spinal cord, and little, if any, effect on the motor nerve endings. The effects of the venom on the circulation were found to be of minor importance compared with those on the respiration.

A WELL-ATTENDED meeting of the medical officers and dental surgeons attached to the Metropolitan Provident Medical Association was held at the head office, 5, Lamb's Conduit Street, on Tuesday. Mr. Francis Buxton, Chairman of the association, presided, and there were also present Sir William Bousfield, Mr. C. G. Montefiore, Mr. A. L. Leon, Mr. W. E. Darwin, and Colonel Fellows, representing the Executive Committee. A resolution was unanimously passed approving of the action of the association in bringing to the notice of the London County Council the work and aims of provident dispensaries. It was also resolved: "That in the event of the London County Council applying to the Metropolitan Provident Medical Association to undertake the medical treatment of school children through the provident dispensaries of London, the medical officers would heartily co-operate with the association, and would do everything possible to meet the requirements of the educational authorities." A medical committee, consisting of Drs. G. Michael, S. Wilson, H. H. Sturge, H. Taylor, J. A. P. Barnes, G. M. Bluet, and Messrs. C. N. Bayfield and H. A. Matheson, dental surgeons, with power to add to their number, was formed to assist the Executive Committee in arranging the details of any scheme of co-operation which may be suggested between the provident dispensaries and the London County Council.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on February 19th, Dr. de Havilland Hall in the chair. The accounts presented showed that the operations of the society in January were more than usually successful. The amount of new business obtained was not so great as in January, 1908; but last year was a record in this respect, and some diminution of numbers in this item was to be expected. On the other hand, the sickness experienced was less than the average expectation; the claims received were for the most part of short duration, and, as more than one of the chronic cases have lately been removed by death, the sickness was not so heavy as at this time last year. The threatened epidemic of influenza seems to have nearly, if not entirely, disappeared, and the claims on the society this year so far have arisen mainly from the throat and chest affections to which medical men are specially subject in severe weather. At the annual general meeting of the members, to be held at the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, London, W., on May 27th, at 4.30 p.m., a satisfactory report will be presented. It will show that in the year 1908, more new members were obtained than in any previous twelve months of the society's working; and that the sickness branch, in which alone new business is now transacted, obtained a substantial addition both to the number assured and the amount of the financial reserves. Prospectuses and all further information on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

LITERARY NOTES.

It is announced that it is proposed to publish a short life of the late Sir William Broadbent. Lady Broadbent will be grateful if any one who has letters from him of general interest will kindly allow her to see them. They should be sent to her at 9, York Terrace, Regent's Park, London, N.W., and will be returned as soon as possible.

To the March number of the *Cornhill Magazine* Mr. Leonard Huxley contributes an article on the author of the *Origin of Species*. In it he speaks of the occasional intractability of Darwin's pen, which called forth the following humorous criticism after a re-reading of the *Origin*:

Exposition was not Darwin's forte, and his English is sometimes wonderful. But there is a marvellous sagacity about

him—like that of a sort of miraculous dog—and he gets to the truth by ways as dark as those of the heathen Chinese.

We suppose this quotation is from Thomas Henry Huxley. An account of Darwin's method of composition may be interesting. In his life of his famous father, Mr. Francis Darwin says that in writing a book Charles Darwin would spend much time and labour in making a skeleton or plan of the whole, and in enlarging and subclassing each heading. In his *Life of Erasmus Darwin*, as it was first printed in slips, the growth of the book from a skeleton was plainly visible. The arrangement was altered afterwards, because it was too formal and categorical, and seemed to give the character of his grandfather rather by means of a list of qualities than as a complete picture. It was only within, says Mr. Francis Darwin, the last few years that he adopted a plan of writing which he was convinced suited him best—namely, writing a rough copy straight off without the slightest attention to style. It was characteristic of him that he felt unable to write with sufficient want of care if he used his best paper, and thus it was that he wrote on the backs of old proofs or manuscript. The rough copy was then reconsidered, and a fair copy was made. For this purpose he had foolscap paper ruled at wide intervals, the lines being needed to prevent him writing so closely that corrections became difficult. The fair copy was then corrected, and was recopied before being sent to the printers. Then came the work of revising and correcting the proofs, which his father found especially wearisome. It was at this stage that Darwin first seriously considered the style of what he had written. When this was going on he usually started some other piece of work as a relief. The correction of slips consisted in fact of two processes, for the corrections were first written in pencil, and then reconsidered and written in ink. When the book was passing through the "slip" stage he was glad to have corrections and suggestions from others. Mrs. Darwin looked over the proofs of the *Origin*. In some of the later works his daughter, Mrs. Litchfield, did much of the correction. After his sister's marriage, most of the work fell to Mr. Francis Darwin's share. Mrs. Litchfield says that her father did not write with ease, and was apt to invert his sentences both in writing and speaking, putting the qualifying clause before it was clear what it was to qualify. He corrected a great deal, and was eager to express himself as well as he possibly could. Perhaps, says his biographer, the commonest corrections needed were of obscurities due to the omission of a necessary link in the reasoning—something which he had evidently omitted through familiarity with the subject. Not that there was any fault in the sequence of the thoughts, but that from familiarity with his argument he did not notice when the words failed to reproduce his thought. He also frequently put too much matter into one sentence, so that it had to be cut up into two. On the whole, Mr. Francis Darwin thinks the pains which his father took over the literary part of the work was very remarkable. He often laughed or grumbled at himself for the difficulty which he found in writing English, saying, for instance, that if a bad arrangement of a sentence was possible he should be sure to adopt it. He once got much amusement and satisfaction out of the difficulty which one of the family found in writing a short circular. He had the pleasure of correcting and laughing at obscurities, involved sentences, and other defects, and thus took his revenge for all the criticism he had himself to bear with. He used to quote with astonishment Miss Martineau's advice to young authors—to write straight off, and send the MS. to the printer without correction, but in some cases he acted in a somewhat similar manner. When a sentence got hopelessly involved, he would ask himself, "Now, what do you want to say?" and his answer written down would often disentangle the confusion. His style has been much praised; on the other hand, at least one judge remarked that it was not a good style. Mr. Francis Darwin says of it:

It is, above all things, direct and clear; and it is characteristic of himself in its simplicity, bordering on naivety, and in its absence of pretence. He had the strongest disbelief in the common idea that a classical scholar must write good English; indeed, he thought that the contrary was the case. In writing he sometimes showed the same tendency to strong expressions as he did in conversation. Thus, in the *Origin*, p. 440, there is a description of a larval cirripede, "with six pairs of beavi-

fully constructed natatory legs, a pair of magnificent compound eyes, and extremely complex antennae." We used to laugh at him for this sentence, which we compared to an advertisement. This tendency to give himself up to the enthusiastic turn of his thought, without fear of being ludicrous, appears elsewhere in his writings.

As for ourselves, we think Darwin's style, with its simplicity and absence of "fine writing," almost perfect for the object he had in view. The pains he took to express his ideas clearly should be a lesson to all scientific writers.

THE RADIUM INSTITUTE.

OFFICIAL STATEMENT.

We have received the following official statement for publication:

His Majesty the King has been graciously pleased to become the Patron of the Institute.

The following additions have been made to the Committee: The Hon. Walter E. Guinness, M.P., as the representative of Lord Iveagh; Felix Cassel, Esq., K.C., as the representative of Sir Ernest Cassel.

A site has been acquired in Riding House Street, Portland Place, upon which the necessary building will be erected with as little delay as possible. The architect is T. P. Figgis, Esq., F.R.I.B.A.

In general terms, it may be said that the Institute will be conducted upon the lines of the Radium Institute in Paris. In addition to the superintendent, the assistant to the superintendent, and the director of the laboratory, there will be an honorary medical and surgical staff (not yet appointed).

The Institute hopes to acquire radium to the amount of 5 grams.

The treatment carried out in the Institute will be strictly limited to treatment by radium or other radio-active substances. Treatment of cases by the Roentgen rays, the Finzen light, and by electrical currents will have no place in the Institute, as such measures of treatment are already very amply provided for elsewhere.

The building will be in two parts, with separate entrances. One section will be devoted to necessitous patients, and the other to the well-to-do. The former will be treated free: the latter will be required to pay fees on such a scale as the medical and surgical staff may determine.

Necessitous patients must bring a certificate from a medical practitioner stating the nature of the case and the fact that the individual is unable to pay for any necessary treatment.

Well-to-do patients should, whenever possible, be accompanied by the medical practitioner under whose care they are. Failing such personal attendance, each patient must bring a letter, stating the particulars of the case, from his or her medical adviser.

Indeed, no patient, poor or well-to-do, will be treated in the Institute except upon the imprimatur of a qualified medical man.

It is hoped that medical practitioners will associate themselves with the specific treatment carried out at the Institute on their individual patients.

Demonstrations in the use of radium will be given, and medical practitioners can be advised as to the mode of employment and as to the radio-activity of their own specimens of radium.

Further particulars will be published at a later date.

British Medical Journal.

SATURDAY, MARCH 6TH, 1909.

THE TREATMENT OF CANCER.

THE scientific surgeon cannot yet sigh, like Alexander, for fresh realms to conquer. Since the principles of the treatment of wounds laid down by Lord Lister have been generally adopted, his knife has invaded nearly every part of the body, and has dealt successfully with many forms of disease which used to be regarded as inevitably fatal. But cancer still to a large extent remains the mere despair of surgery. Operations are, indeed, done for malignant disease which could not justifiably have been attempted in pre-antiseptic days; technical details have been perfected, and many satisfactory results have been recorded. But a cure that can safely be called definitive is extremely rare, and the causation of the disease, without which effective treatment is impossible, has not yet revealed itself to the many keen eyes that are eagerly striving to penetrate the mystery which surrounds its origin. The labours of the investigators engaged in the search have certainly not been fruitless; much has been learnt about the mode of development and dissemination of the disease, its manifold varieties, and the ultimate fate of its constituent elements. But even if it be assumed that there is a fallacy in the belief which often finds expression, that the prevalence of cancer is increasing, it must be admitted that no reduction in the death-rate from the disease has yet been effected. It is also still true as a general proposition that a diagnosis of cancer virtually means a death sentence to the sufferer. This fate may overtake him swiftly, or may follow him with the halting but untiring foot which the poet gives to justice: but, unless he has the good fortune to be cut off by some more merciful ailment before his enemy comes up with him, in the end the disease is pretty sure to run its quarry to death. In the meantime the victim lives under the shadow of a dark foreboding:

Like one that on a lonesome road
Doth walk in fear and dread,
And, having once turned round, walks on,
And turns no more his head;
Because he knows a frightful fiend
Doth close behind him tread.

While it is one of the worst forms of cruelty to delude those under the doom of cancer with hopes of cure, it is the duty of the medical profession to work steadfastly at the problem. It must not allow itself to fold its hands and acquiesce in failure. "Impossible!" Napoleon used to say; "never utter 'that fool of a word before me.'" The saying might well be the motto of those who give themselves to cancer research. There are signs which appear to indicate that, if we are not yet near a final solution, we are at last on a path that may lead to discovery of the secret so long and so jealously hidden.

It is in the hope of encouraging all practitioners of the healing art to fresh efforts in the struggle against cancer that we publish in the present issue

several papers in which the subject is dealt with from different points of view. Sir Hector Cameron rightly holds that while the pathologists are hard at work, it is equally incumbent upon those whose experience has been wide enough to make known the lessons which it has taught them. The publication of operations while the surgeon's knife is yet, figuratively speaking, dripping with blood, is not only misleading, but calculated to bring surgery into contempt. But the fruits of an experience extending over forty years and ripened by ever-growing knowledge, are beyond all price. Unfortunately this is just the kind of information which it is most difficult to procure. The profession, therefore, owes a debt of gratitude to Sir Hector Cameron for supplying such valuable material from his carefully garnered store. One point which must strike every reader of his address is that he has shaken himself free from the trammels of classical teaching as to what constitutes a cure. As he well says, cancer is one of the most contradictory of all diseases. It refuses to be bound by any formula in regard to the period of time beyond which recurrence may be regarded as unlikely. Some of his cases strikingly show the untrustworthiness of the three-year limit. In one of them the patient, after living free from the disease for twenty-seven years, was again attacked, but survived a second operation five and a half years. In another there was no recurrence for nearly twelve years, and then the disease appeared in an unrelated part of the body. In a third case no recurrence took place in the part first affected, but nearly nine years later the corresponding organ was invaded; more than two years have now elapsed without any further development. Other cases are cited by Sir Hector Cameron in which recurrence took place many years after removal. It may be a question whether in these cases the later outbreak of the disease was connected with its original manifestation. Not so long ago the surgeon would have thought the matter settled by saying that the patient had a cancerous diathesis. Sir Hector Cameron, with the modesty born of the true scientific spirit, does not think he has solved the question in this easy fashion. He admits the possibility of a second invasion, but in other cases—notably in that of the patient who lived nearly thirty-three years after the first operation—he thinks the later growth sprang from a residue of the first one traversing the subpectoral fascia. But, as he says, we do not know why it remained so long inactive; "we neither understand its long sleep nor its 'awakening.'" He uses these cases to point the moral that "whether we operate obviously late in the 'disease, whether by limited or extensive removals, 'we must remain uncertain of the results.'"

Another instructive point is brought out by Sir Hector Cameron when he relates cases showing that a mammary cancer may produce extensive involvement of the lymphatics before it is of a size which renders it demonstrable. He concludes that *a fortiori* a tumour so small that it has but recently attracted the patient's attention must not be looked upon as necessarily a very favourable one for operation. As he pithily puts the matter, "small size and recent origin 'are by no means convertible terms.'" Sir Hector Cameron discusses with commendable frankness another aspect of operation for cancer—that is to say, its possible effect in promoting what he calls "destructive dispersion" of the disease. There are cases in which this result seems to be fairly attributable to the operation, and as he says, "the clinical fact

"is enough to make us, as far as possible, avoid all "undue pressure upon and squeezing of the tumour. "whether during diagnostic manipulation or during "the operation for its removal."

Sir Hector Cameron's experience comprises a good many examples of the disappearance and cure of cancerous lesions quite apart from any treatment; he says that in these, for some inexplicable reason, dissemination does not reach internal organs. The key to the mystery here referred to by the distinguished Glasgow surgeon is, we think, furnished by Mr. Sampson Handley, in whose most interesting lecture on the Natural Cure of Cancer the doctrine that "the progress "of a cancer is normally accompanied by retrogressive "or curative processes" is elaborated and illustrated. The natural history of a cancer is, he says, one of centrifugal growth followed by centrifugal death. Unfortunately for the patient, in most cases the self-curative process fails to overtake the centrifugal spread or permeation, and so fails to arrest the march of the disease. In fact, the patient dies before the disease has time to cure itself. But this does not happen in all cases, and Mr. Sampson Handley shows that there is a gradation in destructiveness in cancers of different types, ranging from the medullary carcinoma of young people, in which the cells possess a high degree of proliferative power, to the atrophic scirrhous of old people, whose connective tissue is poor in cells and the cancer is of low proliferative power. The natural local cure of cancer is, according to Mr. Handley, brought about by fibrotic processes which cut off the cancerous epithelium from the contact with connective tissue cells which is necessary to maintain its vitality. As we understand him, it is this process of perilymphatic fibrosis which, if completed in time, prevents dissemination of the cancer. An attentive study of Mr. Handley's paper can scarcely fail to convince any reasonable person of the futility of most of the methods of treatment by which cancer has been said to be cured. As he says, "the "literature of cancer therapeutics does not contain "the record of a single fact which cannot be paralleled among the histories of untreated cases." He thinks, however, that the x rays have an effect in promoting the natural tendency to fibrosis in masses of malignant tissue. Mr. Sampson Handley has seen great apparent benefit in patients suffering from cancer, result from a change of residence from town to country, and he thinks the open-air treatment may be worthy of trial in the more chronic cases of inoperable cancer. But he warns us that in no circumstances whatever should the treatment be recommended as a substitute for operation when surgical intervention is possible.

The spontaneous disappearance of tumours in mice after successful inoculation has been recorded by Dr. Bashford, and examples occurring in the human subject have been reported by Mr. Pearce Gould, Mr. Langlow, Mr. H. J. Waring, Mr. Bruce Clarke, and others. Dr. Bashford has shown that the activity of cancer cells waxes and wanes, and that they are much more vulnerable in the negative phase through the increased resistance induced in the soil. Dr. Bashford foresees a still remote possibility that dissemination from the primary focus may be hindered, but he sees no probability that the primary focus will be got rid of by other means than early surgical removal.

The knife, used before it is too late, is still, therefore, the only method from which satisfactory results can be expected, unless it be in the very exceptional

cases in which Nature may heal without the help of surgery. These researches, however, seem to point the way to the discovery of some means whereby Nature may be assisted in working the "miracle of cure."

Holding to the principle that everything offering a reasonable prospect of alleviation in so intractable a disease should be made known, we publish some cases in which Dr. Fenwick of Accrington records good results from the use of potassium bichromate. The diagnosis in most of them is based on examinations made by the Clinical Research Society. We have satisfied ourselves that the cases are reported in good faith. They might with advantage have been related in fuller detail; but, such as they are, we think it our duty to present them to our readers.

THE LONDON UNIVERSITY, THE COLLEGES, AND THE MEDICAL FACULTY.

We are enabled this week to publish a report by a strong joint committee presented to the Royal Colleges of Physicians and Surgeons in London, and adopted by those colleges shortly before Christmas, propounding a scheme for establishing a system of conjoint examinations between the Royal Colleges and the University. The report would appear to have been drafted before it was known that the Senate of the University intended to ask for a Royal Commission, and it is therefore in the main directed to indicating the way in which the proposal might be carried out under the existing statutes of the University.

The report expresses the opinion that it is desirable that the system of teaching and examination in London should be so co-ordinated as to reduce the number of examinations, and points out that the general character of the examinations of the University and of the Conjoint Board is very similar. The suggestion is that the Royal Colleges should be associated with the University in conducting the preliminary scientific, intermediate, and final examinations for the pass degrees of M.B., B.S., and M.D., leaving to the Colleges the right to grant diplomas to persons ineligible or not desiring to obtain degrees, and to the University its existing rights as to the granting of degrees, while asking it to exercise them as regards its pass degrees conjointly with the Royal Colleges so far as students who have been at least four years in London are concerned. It will be seen that these proposals involve the assumption that the University will grant honours degrees in medicine and surgery, and there can be no valid objection to them on this score. The concluding paragraph of the report states that the Royal Colleges will lay their views before the Royal Commission, and also ask the University to appoint delegates to discuss the question, so that if possible the representations made to the Royal Commission may be joint representations of the Colleges and of the University. The scheme as set forth in the report is, of course, a mere outline, though it ought not to be very difficult to fill in its details; but we again venture to say, at the risk of wearying by repetition, that unless the University can be induced or compelled to substitute for its present matriculation examination one arranged on more practical lines, and in harmony with the conditions imposed on the public and other secondary schools by the regulations of other universities and of the public services, no scheme can be expected to succeed in placing within the reach

of the majority of London students a degree in medicine. Granted that sufficient attention is directed to this point in the representations made by the Colleges to the University and to the Royal Commission, it seems reasonable to hope that the long-desired co-operation which the existing statutes authorized the University to bring about, and which it has failed to bring about, may become an accomplished fact.

It was mentioned a fortnight ago that a memorandum was in course of circulation outlining a scheme for the formation of a Faculty Board to act as the representative committee of the Medical Faculty of the University. The text of this memorandum and of the resolution to be proposed at the meeting of the Faculty on Friday will be found on pp. 636, 637, and it will be observed that the resolution is to be proposed and seconded respectively by two members of the Faculty who may, perhaps, be said to represent opposing parties. When the University was reconstituted ten years ago, Boards of Studies composed of teachers were appointed with a view to carrying out one of the many objects of the reconstitution, which was to give to the teachers their due influence in the determination of the curricula and examinations, and so to make the University a teaching body. The general assemblies of the Faculty were given practically no power beyond that of electing to the Senate a certain number of members who were also members of the Academic Council. The recommendations of the Boards of Studies were not to be considered by the Senate until after they had been reported upon by the Academic Council in the case of internal students, as the vast majority of medical students are. The Academic Council consists of representatives of all the Faculties, and it has become customary to refer any matter affecting a particular faculty to a subcommittee consisting of the representatives of that Faculty—that is to say, in the case of medicine to three persons, who cannot, of course, be cognizant of all the aspects of all questions affecting the Faculty of Medicine. Moreover, the medical members form a small minority on the Academic Council, a body largely concerned with routine business.

Among the causes which have retarded the development of the University on its medical side has been the fact that the Medical Faculty is itself too large and unwieldy a body to utilize the only weapon put into its hands—the power to consider reports of Boards of Studies and offer advice to the Senate upon them. On the other hand, the Academic Council is too small, and the representation of each faculty upon it is neither adequate nor representative of the varied interests involved; moreover, it is overburdened with detail, and consequently has neither time nor energy for its proper charge, which is the consideration of questions affecting the whole University and all the Faculties. The Cowper Commission suggested the formation of Faculty Boards consisting of persons elected by the faculty in sufficient number to include representatives of the various branches of medical study. Under the present constitution it is not possible to appoint an official Faculty Board with executive functions, and the need for such an executive committee will no doubt be impressed upon the Royal Commission; nevertheless it will be possible for the Medical Faculty by general consent at once to delegate its advisory functions to such a committee, which might be called a Faculty Board, and the Senate might be requested to regard this Faculty Board as the delegate of the Faculty itself, and

therefore as the chief advisory body in medicine. The experience gained by the working of such an advisory committee would be a valuable guide to the Royal Commission in finally deciding the scope of the powers and duties of a statutory Faculty Board.

In order to obtain representation of all the different subjects of the medical curriculum it would be necessary to have a rather large Faculty Board; the memorandum suggests 24 to 30, about one-third representing the preliminary and intermediate medical subjects, and about two-thirds the final studies. It may be argued that the appointment of the Royal Commission renders the proposed action at the present time unnecessary, but the answer to this is that the Royal Commission cannot be expected to report for some considerable time, and that after it has reported there must be a further delay before its recommendations can be carried out. Meanwhile, the paralysis of the University on the medical side will continue, and as this paralysis appears to be in part, at least, due to an easily removable cause, there seems no ground for refusing this palliative treatment while awaiting the more drastic surgical measures which the Commission may be expected to apply.

THE MILITARY MEDICAL SERVICES.

MR. HALDANE, in his memorandum relating to the army estimates for 1909-10, has introduced a paragraph discussing the loss of the British army in the United Kingdom, India, and the Colonies, by death and invaliding. He has dealt with the matter fully this year because he considers that we are sufficiently removed from the disturbing influence upon normal statistics of the South African war to contrast the wastage from deaths and invaliding at the present day with that of the period preceding the war. In the memorandum the statistics for 1898 are contrasted with those for 1907, the last year for which returns are at present available, but we have thought it well to set out the figures year by year (see page 635). They show a remarkable diminution in the loss by disease, both loss of life and loss of service. The fall in rates of admission to hospital of constantly non-effective from sickness is partly to be attributed to an administrative improvement by which men with slight ailments are treated in barracks as out-patients. The true effect of the efforts at disease prevention which were redoubled and systematized as the result of the reforms in the Royal Army Medical Corps instituted in 1902 are best seen in the death and invaliding rates. The most conspicuous effect on the death-rate is to be observed in the Indian returns; in 1888 the ratio of deaths per 1,000 of strength in India was 15.20; in 1898 it was 20.31; a steady fall has been maintained since 1903, and the rate in 1907 was 8.38. The ratio discharged as invalids has followed a very similar course: in 1888 it was 12.43; in 1898 it was 19.94; and in 1907 it was 8.84. The decline in the death-rate among British troops serving in the colonies, including the force in Egypt, has also been conspicuous; it was 8.46 in 1888, and 5.16 in 1907. In the United Kingdom there has also been a decline both in deaths and invaliding, but the death-rate in earlier years was much lower in this country than in the colonies, and the scope for improvement therefore narrower. As Mr. Haldane points out, the improvement is not only welcome as indicating the increased wellbeing of the soldier, but as implying an all-round saving in the cost of the

army, since it means a reduction in the number of hospital beds, fewer men maintained in peace to produce the given number fit for war, and smaller annual drafts to be sent abroad.

The improvement is, we believe, to be attributed to a new spirit in the army, a recognition of the essential part which an efficient medical service can play in obtaining an efficient army, and in maintaining its efficiency both in peace and in war. We have said advisedly that a new spirit exists in the army, for we believe that the new conception has been accepted by officers of all branches who take a serious professional view of their calling. The fundamental principle is that the medical corps of an army is concerned with the maintenance of its fighting strength. The medical corps has, therefore, three classes of duties—therapeutic, military, and sanitary—using these terms each in its widest sense. The military medical officer of to-day after joining receives a very thorough training in his special duties, and the whole trend of this training is to impress upon him that his corps is an integral part of a great organization, all the branches of which are working towards a common end, which is to put and keep an efficient army on foot. He learns that in war his corps is responsible for the administration of the large army of non-effectives who are produced—and, it may be added, produced with such startling rapidity—in all campaigns; that his corps is responsible for the treatment of injury or illness which has rendered a man non-effective, for his removal from the fighting lines, his transmission along the line of communications to the base, and his final disposal either by return to duty or by return home as an invalid. The corps, therefore, is responsible for the details of the treatment, removal, clothing, and feeding of the non-effective; and the re-arming and reclothing of the man who recovers his health and can return to the ranks. Further, in peace he learns that it is through his corps that the soldier is enlisted, and through it in many instances discharged; that the selection of soldiers is a grave responsibility, and that the diminution of wastage by the prevention of unnecessary invaliding is a most important element in the economy and efficiency of an army. Both in peace and in war he is taught to realize that upon his knowledge, efficiency, and zeal must depend to a very large degree the extent to which the prevention of disease, and especially of such diseases as typhoid fever, which has always been the scourge of armies in the past, can be carried out. The success in the prevention of disease in an army is not a matter entirely in his hands; without the hearty and intelligent co-operation of military officers in all branches and grades complete success is not possible, but we believe that we have been justified in the statement that there is a new spirit in the army generally, and that it has resulted in an approximation of medical to general army administration. The relation of medical to general army work is studied by modern staff officers, and the co-ordination of combatant and medical duties is making satisfactory progress.

Mr. Haldane has told the country that what it wants is a small and efficient army, organized and administered on scientific methods, and ready for service abroad, and he, at least, clearly recognizes that scientific efficiency is impossible unless the multifarious duties which fall to the lot of the medical

corps are adequately discharged, and that they cannot be adequately discharged unless the staff of medical officers is maintained at sufficient strength, and unless these officers are encouraged, and required, to cultivate the special knowledge and experience which is necessary for the due discharge of their special duties.

If and when this country is involved in war the regular army will have to take the field, its place must be supplied by the Territorial Force; in that force the place of the Territorial Medical Corps will be not less important than in the regular army; in fact, it will be almost precisely the same. It will have the same administrative and scientific duties, the same obligation to protect the soldier from disease, and the same responsibility for his safe transfer when sick or wounded from the fighting line to the general hospital.

DEATH CERTIFICATION.

EVERY year brings fresh evidence of the necessity of legislation in connexion with the registration of deaths and the law relating to burials. We are, therefore, glad to see that Mr. George Greenwood has again introduced his Deaths Registration and Burials Bill. Last year it had no chance of passing into law, much as it is needed, but we hope that this year better fortune may attend it. The bill proposes to give effect to the recommendations of Sir Walter Foster's Committee of 1893. Under it no death could be registered without a certificate of death signed by a registered medical practitioner or the public certifier of deaths appointed under the Act, or a proper verification certificate of death signed by the public certifier of deaths. The bill provides also for the appointment of a public certifier of deaths in every Poor Law union, who must be a registered practitioner, and who would be responsible for the verification of the fact of death in all cases. The bill would also make it impossible for any body to be buried without a certificate from the registrar of deaths or from a coroner sent directly to the burial authority, which would have to be returned to the registrar endorsed after the burial. The bill also provides for the registration of stillbirths and the form of death certificate, and legalizes penalties for non-compliance with the provisions of the measure. In some quarters it may be held that this subject is under the consideration of the Departmental Committee now considering amendments on the law relating to coroners. Even if this be so, Mr. Greenwood's bill suggests to that Committee the directions in which the law can best be amended; and while the Government will no doubt await the report of their Committee before taking action, we would urge, in the interests of the public, that any great delay is unjustifiable. Legislation has been overdue for years, and the manner in which this subject has been neglected by successive Governments for more than fifteen years after an authoritative report on the evils of the present system, has become a scandal. Under the existing law crime often escapes detection. More than once this has been painfully illustrated in criminal trials. Even now over 8,000 deaths are uncertified every year, and the slow rate of improvement is illustrated by the figures for the last ten years for England and Wales. The uncertified deaths for 1897 were 11,103; for 1898, 10,441; for 1899, 10,745; for 1900, 11,257, and for 1901, 9,936. In answer to a question put in the House of Commons on Monday last by Mr. George Greenwood, the President of the Local Government Board has

brought these figures up to date in the following table:

Year.	Total Number of Deaths.	Number of Uncertified Deaths.	Proportion per 100 of Uncertified Deaths.
1902	535,538	9,654	1.80
1903	514,628	8,721	1.69
1904	549,784	8,882	1.62
1905	520,031	8,446	1.62
1906	531,281	8,114	1.53

These figures show, it is true, a slow improvement. In the first five years there were 53,532 uncertified deaths as compared with a total of 43,817 in the second quinquennial period. This is good so far as it goes, and has been produced by complaints made from time to time by the General Medical Council and by the British Medical Association. The Registrar-General has been braced up to stricter administration of a defective law. But the evil can never be adequately dealt with until a new and more strict Act has been placed on the Statute Book. Under the present, crime can escape detection, deaths are registered and bodies are buried under conditions that do not secure safety for the public or accuracy for statistical records. It is time that a loose and imperfect system was mended, and we urge upon the Government the necessity of dealing with the subject speedily and drastically.

THE WANING OF CONSCIOUSNESS UNDER CHLOROFORM.

DR. ELMER E. JONES, of Indiana University, has contributed an interesting paper to the *Psychological Review* on the waning of consciousness under chloroform. He gives the results of three introspective studies on himself during the administration of the anaesthetic. At the first inhalation, he says, there are marked sensations in the region of the heart, the contractions of which become violent and accelerated. Immediately accompanying these sensations a peculiar stupefying feeling pervades the whole body. In regard to the order in which the various types of consciousness disappear there are, he believes, two sharply defined stages: first, the complete damping down of all the sense organs, so that there is no communication with the outside world; secondly, the disappearance of memory, all types of imagery, associational processes, reason, and isolated ideas. In the very earliest stages of anaesthesia the visual sense was slightly stimulated, the colours in the spectrum appearing a little brighter, letters and figures somewhat clearer and the light in the operating room a little more intense. Hearing for the first few minutes was almost normal, save for a slight roaring which for a considerable time did not appear to interfere seriously with perfect audition. At this early stage various movements were made to test the kinesthetic sensations. For the most part these sensations appeared normal, though to innervate seemed difficult, and to initiate a movement seemed slightly fatiguing. There also appeared in the movements themselves two illusions: all movements made appeared to be much longer and much slower than they actually were. The tactile sense in the early stages seemed slightly dulled to the touch of the pointed instrument, yet it could be accurately localized. At the close of the first two minutes there was a general bodily stupor, accompanied by decidedly pleasant feelings throughout. Dr. Elmer Jones says that, in the three tests made by him, the

first sense to break down under the influence of chloroform was hearing; while vision was still perfectly clear, and the tactile sense only slightly blunted, audition had begun rapidly to wane. All the deeper conscious states were perfectly normal at that time. Memory was not impaired, the imagination was very active, and figures were added up with as much ease as under normal conditions. With the disappearance of the tactile sense and hearing the body had completely lost its orientation. It appears to be simply floating in space. Dr. Elmer Jones describes this as a most ecstatic feeling. His feelings corresponded very closely to Cardinal Newman's description of death in the *Dream of Gerontius*, when he says:

Down, down, forever I was falling, through
The solid framework of created things.

Closely following the disappearance of the tactile sense all muscular control was lost. But, after all movements had ceased, it was still possible to send the impulse to the proper muscles from the motor centres in the brain; at least, there was a distinct feeling of the impulse so moving. The last movements to disappear were the most highly specialized; the fingers could be moved for a considerable time after the biceps and triceps refused to contract; the organs of speech could be innervated to movement a considerable time after most other muscles refused to act, but, of course, speech was defective. The movements of the tongue and eyes were the very last to disappear. At this stage of the anaesthesia the sense element in consciousness had practically been eliminated, but there still remained an inner consciousness which for the most part was perfectly normal. At this point there appeared a pretty general disintegration of ideas, and all associations seemed considerably broken. Ideas disappeared very rapidly, leaving an entire blank. These lingering ideas were some of the very earliest gained in life. They were so vague and indistinct that they could scarcely be recognized, yet the fact that they remained so long as the residual of weakened cerebral activity shows how deep-seated they are in the mental constitution. Dr. Elmer Jones thinks his observations throw light on the psychology of death. But, after all, experiences under anaesthesia are such stuff as dreams are made of. From the sublime thoughts that came to him while under the influence of chloroform Oliver Wendell Holmes thought he would be able to solve the riddle of the universe. Placing himself in his arm-chair, with pen, ink, and paper at hand, he inhaled the anaesthetic. As drowsiness stole over him, the nature of things seemed revealed to him. By a vigorous effort he seized his pen and wrote, he knew not what, for before he had finished he fell back unconscious. When he awoke, with trembling anxiety he turned to the sheet of paper, on which he could read in scrawling characters, but quite legible, the secret he wished to know disclosed in the following oracular words, "A strong smell of turpentine pervades the whole!"

THE LIGHTING OF SCHOOL ROOMS.

THIS important question has been studied in America and Continental countries perhaps more carefully than in England. The city of Boston in 1907 appointed an expert committee consisting of three ophthalmic surgeons and two electricians to carry out experiments to determine the best method of lighting school rooms, and the chairman, Mr. Miles Standish, has published an account of its work and conclusions in *Ophthalmology*. It is not difficult to arrange the light for a single desk; it should be sufficient in strength, it should come from the left side, it should not be reflected from the paper into the eyes of the student

and, though the light upon the book should dominate, the general illumination of the room should be nearly as great as that upon the paper to avoid too great a contrast. In the school room the problem is more complicated, for from forty to sixty desks have to be illuminated. The first requisite is good general illumination, and this must depend upon the style of decorating and furnishing adopted. The best colour for the walls is a pale yellow-green, or buff, the latter being perhaps more suitable for both day and night work. The "window shades," which are, we fancy, what we should call "blinds," should be "hand-painted" grey-green, which is the best colour to exclude the direct sun by day and reflect the illuminant at night. The desks should be of light-coloured wood, but the surface should not be polished. In Germany an attempt has been made to secure a general diffuse illumination at night by throwing a powerful light upon a white ceiling and upon the upper third of the walls. This method demands a brilliant and therefore expensive light, and the absence of shadows has a bad physiological effect. The experiments were made in a room 23 by 28 ft., the walls were painted light yellow, the ceiling white. It was found that it was necessary to have at least nine stations; it was difficult to avoid concentrating the light upon the desks in proximity to these stations, and to eliminate conflicting shadows. A shade called the "Zalinsky," constructed of prismatic glass, coated on the inner or outer surface with white enamel, was found to be the best. Sufficient light penetrated it to properly illuminate the ceiling and walls, but the greater portion was projected downwards at a wide angle. Within these reflectors were placed incandescent bulbs, the lower third or less of the bulb being frosted to hide the filament. When the light stations were properly arranged, it was found that at no desk did the shadow of the pen fall upon the paper, nor did a head ever cause a shadow to obscure the work. With the correct lamp, the candle-power on top of the desk was 2.5. The 40 watt 36 candle-power tungsten lamp was the most efficient as regards illuminating power, and showed a net economy of 45 per cent. when compared with a carbon lamp. Attention is drawn to a report by Mr. Bishop Harman to the Educational Committee of the London County Council in 1907, giving an account of how best to illuminate a school by gas. Harman concluded that the shade of a mantle burner must have a spread of 90°; but with an alternating current allowing of a simple static transformer, and the use of high-efficiency metallic filament lamps, the cost of electric lighting should not be much more than that of gas.

THE FOSSIL MAN OF LA CHAPELLE AUX SAINTS.

PROFESSOR MARCELLIN BOULE, palaeontologist to the natural history museum, recently communicated to the French Academy of Sciences a note on the remarkable human remains found in a grotto near to La Chapelle aux Saints by three French abbés, MM. J. Bouyssonie, A. Bouyssonie, and L. Bardon. Professor Boule vouches for the archaeological competence of these gentlemen, and says that there can be no doubt that these bones were found in geological strata corresponding to the middle pleistocene period, and that their antiquity is attested also by their fossilized condition as well as by their morphological characters. The bones comprise a skull broken into numerous fragments, some vertebrae, and certain bones of the limbs. The last indicate an individual of the male sex whose height scarcely reached 1 m. 60 (5 ft. 4 in.). The skull has been satisfactorily reconstructed and shows striking human characteristics; it is dolichocephalic,

the cephalic index is 75; the bones are very thick, the cranial cavity flattened, the frontal bone retreating, and there is an enormous development of the superciliary ridges, which are as prominent as those in the famous Neanderthal skull, and are surmounted by a deep furrow, which extends from one orbital process to the other; the occipital portion of the skull is prominent but much depressed: the occipital foramen is placed far back, and the occipital condyles are flattened, while the mastoid processes are not well marked. The face shows considerable prognathism, the orbits are projecting and large, and the nose, which is separated from the forehead by a deep depression, is short and very broad. The superior maxilla, instead of being hollowed out below the orbits to form the canine fossa, as is the case in all existing human races, protrudes forward, to form, with the prolongation of the malar bones, a sort of snout. The teeth have disappeared, but the palatine vault is very long, and the lateral borders of the alveolar arcade are nearly parallel, as is seen in the anthropoid apes. The lower jaw is remarkable for the great width of the condyle, the slight depth of the sigmoid notch, the great thickness of the body, the obliquity of the symphysis, and the absence of chin. This skull presents all the characters of the crania found at Neanderthal and Spy, and as specimens of this type have now been found at places far removed from one another, it can no longer be contended that they represent merely a pathological condition, as was at one time thought by men of such eminence as Virchow, Carl Vogt, and Quatrefages; they must represent the type of a race of men inhabiting a portion of Europe in the middle pleistocene period. The type differs from any of the races actually in existence, and is much inferior to them. There is no question of any generic difference, but whether a specific distinction should be recognized must depend on what is meant by "species." If the cranium belonged to a monkey, a carnivore, or a ruminant, the characters are so marked that they would justify its classification as a separate species. Professor Boule thinks that such skulls occupy a position midway between the *Pithecanthropos* of Java and the lowest living human races, although he does not imply by this that there is any direct genetic connexion.

THE INTERNATIONAL OPIUM COMMISSION.

THE International Opium Commission which has been sitting in Shanghai has ended its labours and has drawn up a series of resolutions, the substance of which has been telegraphed by the correspondents of the *Times* and of Reuter's Agency. The first resolution recognizes the unswerving sincerity of the Chinese Government in its efforts to suppress the use of opium, the increasing body of public opinion among the Chinese by which these efforts are supported, and the real, though unequal, progress made in a task of the greatest magnitude. The second recognizes that the unrestricted manufacture and sale of morphine is a grave danger, and that the morphine habit shows signs of spreading, and therefore the Commission urges strongly upon all Governments the importance of taking drastic measures to control the manufacture and sale of this and other derivatives of opium. The third resolution, recognizing the importance of the scientific investigation of anti-opium remedies, and of the properties and effects of opium, recommends each Government to take such action in this branch of the subject as it may deem necessary. These three resolutions were submitted by the British delegates. Two other resolutions were

adopted on the recommendation of the American delegates: one of these had reference to the institution of reasonable measures at ports of departure to prevent the shipment of opium or its alkaloids, derivatives, or preparations to any country which prohibits their entry, and the other recommended each Government to apply its pharmacy laws to its subjects in the consular districts and settlements in China. Two other resolutions were submitted by the British and American delegates jointly: one, in view of the action taken by the Chinese and other Governments to suppress opium-smoking, recommended that each delegation should move its own Government to take measures for the gradual suppression of opium-smoking in its own territories, with due regard to the varying circumstances. The other, after stating that the use of opium in any form otherwise than for medical purposes is a matter for prohibition or regulation in nearly every country, and after referring to the fact that there are wide variations in the conditions prevailing in different countries, urges upon each of the different Governments concerned the desirability of a revision of its regulations. The two remaining resolutions, proposed by the Chinese and emended by the French delegates, urge upon all Governments having concessions or settlements in China the suppression of opium divans, and recommend the respective Governments to enter into negotiations with the Chinese Government to ensure the prompt adoption of effective measures in foreign concessions or settlements in China to prohibit the trade in anti-opium medicines containing opium or its derivatives.

MEDICAL MEN AND LEGACIES FROM PATIENTS.

A DOCTOR who benefits by the will of a patient who has been under his care is necessarily, however honourable his conduct may have been, placed in an awkward position. The charge of undue influence is easy to make, and it is one which disappointed relatives are usually eager to bring. It is one that from the very nature of the relations between practitioner and patient is difficult to rebut. It would save a good deal of litigation if the English law were assimilated in this particular to the French law, which treats all bequests to a doctor from a patient as null and void. But the law being what it is, there is no reason why a medical man should not be allowed to benefit by it, and it is the duty of those who administer the law to protect him against injurious imputations. These reflections are prompted by a case which was recently tried before Mr. Justice Bigham. Dr. William Dunn, now medical officer to Uppingham School, but formerly in practice in Battersea, had among his patients there a lady who, when she first came under his care, was living apart from her family in very poor circumstances. Besides advising her as to her health Dr. Dunn lent her money, and Mrs. Dunn tried to make peace between her and those from whom she was estranged. Later the lady inherited a considerable sum of money from a sister, and then she seems to have begun making a number of different wills, sometimes independently, sometimes with the help of various solicitors. The terms of these wills varied, but one feature stood out clearly in them all—the wish to benefit Dr. Dunn, who had befriended her in her evil days. There is no doubt, from the evidence given at the trial, that she was given to drink, but there was no proof that any undue influence was exercised either by Dr. Dunn or his wife in the matter of her testamentary dispositions. It is an important point in the case that Dr. Dunn ceased to have charge of her a considerable time

before her death, and did not see her after April, 1907. The will which was disputed was executed in September, 1906, and between that time and the date of her death, which occurred in June, 1907, she was under other medical care, and had independent legal advice. She had thus plenty of opportunity of changing the terms of her will if she had wished to do so. The trial lasted three days, when the parties came to terms, and the will of September, 1906, was pronounced for. The terms provided for the division of the lady's estate, which amounted to about £10,000. We congratulate all the parties on the settlement of a painful case, and we especially congratulate Dr. Dunn on the virtual acquittal from an odious charge which the settlement involves. We have purposely refrained from going into details of the case as reported in the *Times*. We may be allowed to say, however, that in our opinion Dr. Dunn is perfectly entitled to a legacy which was obviously intended by the poor lady to be a reward for professional and other services rendered by him to her at a time when she was poor and friendless.

THE PREVENTION OF FIRE.

THE great majority of the public is probably quite unaware of the existence of the British Fire Prevention Committee, but for a number of years it has been carrying on work of the utmost public utility. The object of the committee, which consists of experts, is the scientific investigation of the cause, prevention, and control of accidental outbreaks of fire. The committee's method is experimental, and for the furtherance of its ends it has established a testing station in Regent's Park. Here almost any kind of fire can be made under what may be called laboratory conditions, and various methods of extinguishing are regularly tested under the eyes of competent judges. An important part of the committee's work has been the periodic publication of reports in pamphlet form under the title of "Red Books." Two of the most recent of these are, perhaps, of exceptional interest to the public at large. No. 128 describes a series of tests undertaken to estimate the value of such ordinary apparatus as a hand-pump, buckets, jugs, pitchers, and even the humble tumbler, as applied to the kind of outbreak of fire that is usually met with in an ordinary dwelling-house. In each of these experiments the fabric tested was allowed to get "well alight," but was quickly extinguished by the simple means described. It appears, however, that it took generally less than two minutes for the materials used in the experiment to justify the application of the test, so that one is justified in assuming that even five minutes' start in an ordinary bedroom might render such a fire superior of ordinary domestic resources. The important point emerges, however, that the successful extinction of such a blaze depends not only on the quantity of water used, but on the force with which it is pumped or thrown on to the burning material. Pamphlet No. 133 is concerned with the extinction of burning petrol and other volatile and highly inflammable liquids and of celluloid by means of asbestos cloths, sand, and steam. It appears that the value of steam is proportioned to the degree of saturation which can be obtained in the room containing the burning material, and steam under pressure is not of course commonly available. But the extinguishing powers of suitable asbestos cloths are shown to be so remarkable, that it seems as though the provision of one or more such cloths should be made compulsory in garages, dye works, and other places where petrol or other such inflammable substances are stored.

These publications are admirable in their scientific accuracy, and deserve a wider recognition by the large public whom they immediately concern. They can be obtained from the office of the Committee, Waterloo Place, Pall Mall.

WE regret to learn that Mr. Wakley, Editor of the *Lancet*, has been seriously indisposed for the last two months, and that his condition at the present time causes his friends much anxiety.

AMONG the fifteen candidates selected by the Council for election into the Royal Society this year are Sir Thomas Barlow, Bart., K.C.V.O., M.D., Holme Professor of Clinical Medicine in University College Hospital Medical School; Dr. James Lorrain Smith, Professor of Pathology in the Victoria University, Manchester; and Dr. James Thomas Wilson, Professor of Anatomy in the University of Sydney, New South Wales.

AT a meeting of the business committee and the German members of the International Cancer Research Association, held at Berlin on January 4th, it was agreed, on the proposal of His Excellency Professor von Czerny to convene a conference on cancer at Brussels during the exhibition in that city. The final decision was left to the board of directors, which will meet during the session of the German Surgical Congress at Berlin, April 14th to 18th.

WHEN the late Dr. Thomas Peacock died in 1882 the large collection of abnormal hearts he had collected, which form the basis of his treatise on *Malformation of the Heart*, was presented to the Museum of the Royal College of Surgeons. These with the others added before and afterwards make the College collection one of the most extensive in the world. This collection will form the subject matter of three Hunterian Lectures to be given by Professor Arthur Keith, Conservator of the museum, in the theatre of the Royal College of Surgeons, on March 8th, 10th, and 12th, at 5 p.m.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

The Debate on the Address was concluded on Thursday in last week as anticipated. After the Irish amendment had been defeated there was an animated discussion on the imprisonment of British subjects in India, and a division in which the Government had a majority of 119. On Thursday the local taxation question was raised, and many references were made in the course of the debate to the increased expenditure caused by medical inspection of school children. General sympathy was expressed on both sides of the House with the view that local burdens required to be lessened. After a division a further amendment relating to the Congo came on and was withdrawn, and the debate finished with the alien question, which was made the occasion for a strong denunciation of Mr. Gladstone's administration of the Act. He, however, made a very vigorous defence of his action, and had the best of the argument, and after a division the Address was agreed to, and the Commons freed for general business.

The Supplementary Estimates occupied the Commons on the first three days of the week, and the time was mainly occupied with inquiries about the £910,000 required above the estimate for Old Age Pensions. The enormous preponderance of persons over 70 in Ireland as compared with Great Britain was the subject of much comment, and the Chancellor of the Exchequer said that an inquiry was being made into the matter. Many references were also made to the interpretation of medical relief. The vote was eventually agreed to, and a discussion on the estimate

for the unemployed followed. The Supplementary Estimates were not disposed of till Wednesday, and consequently the second reading of the Housing and Town Planning Bill could not be taken.

The London University Commission.—Mr. Ramsay MacDonald asked the President of the Board of Education whether, before nominating a commission to inquire into the London University, he had consulted representatives of London technical schools and polytechnics; and, if so, with what results? Mr. Runciman replied in the negative, and said that it was not considered necessary before nominating the commission to consult representatives of London technical schools and polytechnics on the personnel of the commission or on its reference. Mr. MacDonald then asked if it was not one of the chief purposes of this commission to determine the future status of the Imperial School of Technology? Mr. Runciman said that was distinctly within the terms of reference, and, in reply to a further inquiry as to whether the teachers had not asked to be represented on this commission, he stated that the decision arrived at was that they should avoid appointing a representative commission, but that it would be better to have a judicial commission. If a representative commission had been appointed, it would have been very large and unwieldy; and they had done their best to select a judicial commission.

The Cost of Medical Inspection.—Mr. Ramsay MacDonald asked the President of the Board of Education whether his attention had been drawn to the dissatisfaction of local education authorities regarding the burden which adequate medical inspection of school children would put upon rates, and the failure of the Board of Education hitherto to give what the local authorities considered to be fair financial assistance for this purpose; and whether he could now say what the Board of Education proposed to do, or when he intended to make a statement on the subject. Mr. Runciman replied in the affirmative, and said that many requests were constantly being made for increased grants in relief of local rates. Had either of the Education Bills of last session passed into law, increased grants for educational purposes would have been made to local authorities. He was not in a position to make any statement at present, but the Prime Minister and the Chancellor of the Exchequer had undertaken to receive a deputation on this subject on March 20th.

Pulmonary Tuberculosis.—Mr. Summerbell asked the Secretary of State for War if he was aware that the Local Government Board had issued a general order to local authorities in England and Wales setting out that, whereas tuberculosis was an endemic disease, and that form of the disease which was known as pulmonary tuberculosis was an infectious disease, new regulations were expedient with a view to preventing the spread of that disease; and, if so, could he state whether it was the intention of his department to act on such order in so far as the army was concerned, in view of the fact that some 350 men were discharged from the army each year suffering from this disease, and without receiving any consideration from the War Office, and by so doing give effect to the recommendations made some time ago on this subject by a Select Committee appointed for the purpose. Mr. Haldane replied that if his hon. friend would kindly refer to the order in question (No. 52,712) he would see that the new regulations amounted to instructions in regard to notifications to the medical officers of health of sanitary authorities of cases of pulmonary tuberculosis occurring among inmates of Poor Law institutions and poor persons in receipt of relief from the poor rate. Cases occurring among men discharged from the army had been similarly notified in the past to these officers.

Tuberculosis and Insanitary Schools in Ireland.—Mr. John Murphy asked Mr. Birrell last week how many schools there were consisting of only one apartment in which cookery and laundry work were taught; whether he was aware that there were many insanitary and overcrowded schools, and that a portion of the tuberculosis prevalent in Ireland was directly traceable to the defective atmosphere caused by rebreathed air in such schools. Mr. Birrell

answered that the Commissioners of National Education informed him that the preparation of a return of schools having only one apartment in which cookery and laundry work were taught would take a considerable time. The value of the return would not be commensurate with the labour involved in compiling it. There were many insanitary and overcrowded schools, but the Commissioners had no definite information as to the connexion between such schools and the prevalence of tuberculosis. The Commissioners regarded instruction in cookery and laundry work as a most important part of the ordinary curriculum of national schools, but teachers were not required to teach these subjects when suitable provision for the purpose could not be secured.

Indian Medical Services.—On Tuesday, in reply to Dr. Rutherford, Mr. Buchanan stated that there was no fusion of the two medical services in India in time of war; the services worked separately—the Royal Army Medical Corps with British field hospitals and the Indian Medical Service with native field hospitals. Suggestions for amalgamation had on several occasions received consideration, but they had not been thought likely to lead to reduction of establishment or expenditure, or, if they did, they might involve a risk of a breakdown of the medical organization in time of war.

Experiments on Cats.—Sir Frederick Banbury asked the Home Secretary last week whether a number of painful experiments had been and were being carried on on cats for the purpose of obtaining evidence to lay before the Departmental Committee on Lead Poisoning; and, if so, whether he would state under what certificates they had been performed. Mr. Gladstone replied that two licensees obtained certificates A and E last month to carry out experiments for this Committee. One of these gentlemen, who gave evidence before the Committee in December, had held other certificates (A and E) since 1905, authorizing experiments on cats in connexion with lead poisoning. The objects of the experiments included an inquiry into the channels of infection in chronic lead poisoning and the establishment of better methods of diagnosis—objects which he thought the House would agree to be of great importance. In answer to a further question on Monday as to the treatment and disposal of the cats Mr. Gladstone said that the accounts which he had seen showed that the cats used in the experiments which were brought to the notice of the Committee, but which were not specially performed for them, were killed, some at once, and others after the lapse of a few days. He was not aware that any of the series of experiments authorized on behalf of the Committee had yet been performed, but he was making inquiries.

Vaccination.—Mr. Lupton asked the President of the Local Government Board if he was aware that Albert Shaw, of 114, Sutherland Road, Longton, about 4 months old, was vaccinated about September 15th, 1908, by Dr. Allan; that the child became so ill that after three days Dr. Lefevre had to be called in; and that the child, after great suffering, died on September 26th; if this child was vaccinated with stuff supplied by the Local Government Board; and, if so, what steps he proposed to take to stop the distribution of poisonous vaccination matter. Mr. John Burns said that he had communicated with Dr. Allan, and was informed by him that a child named Albert Edward Shaw, of 114, Sutherland Road, Longton, died on September 26th last, the cause of death being stated in the death certificate as enteritis. Dr. Allan also informed him that he had vaccinated with calf lymph supplied by the Local Government Board a child whose name was entered on the birth register as Morris Shaw, but who seemed to be the child already referred to. The vaccination, however, took place on June 24th last, and not about September 15th as stated in the question. There did not appear to be any reason to connect the death from diarrhoea with the vaccination, which took place more than thirteen weeks previously.

The Story of a Tramp.—Mr. Cooper called the attention of the President of the Local Government Board and of the Home Secretary to the death of a tramp who died in prison from heart failure following pneumonia, and asked

if they were aware that Andrewes had been an inmate of the Croydon casual ward, and when his time expired said he was too ill to continue his journey; whether the officials of the Croydon Union refused to listen to his complaint; whether he was seen or examined by any medical officer of the Croydon Union; was he aware that Andrewes, after being turned out of the casual ward, broke a window so that he might get locked up to get proper medical treatment, and was sentenced by the Croydon magistrates to seven days' hard labour; whether the Croydon Board of Guardians had made any inquiry into Andrewes's statement; and, if not, what did he intend to do in the matter? Mr. Burns replied that he had seen a copy of the depositions taken at the inquest, and he had made inquiry with regard to the case. It appeared that on the day on which Andrewes's time was up for leaving the Croydon casual ward, he said that he did not feel well, and that he could not go on his journey. He was consequently examined by the workhouse medical officer, who did not find anything wrong, and thought he was fit to continue his journey. The medical officer told him he did not consider the case one for infirmary treatment, but if he wished to become an inmate he should apply to the relieving officer for an order of admission. It was the fact that almost immediately afterwards he broke a window in the workhouse, and was sentenced to seven days' hard labour for wilful damage. The medical officer stated that he attended the police-court and gave evidence as to the physical condition of the man, who made no complaint then of being ill, and did not appear to be so. The matter had been fully inquired into by a subcommittee of the Visiting Committee of the workhouse specially appointed for the purpose, and the statement of the medical officer appeared to be supported by the other statements made to them. Mr. Gladstone, in answer to a similar question, said that he had made inquiry into this case, and was informed that Andrewes, having complained when in the casual ward at Croydon that he felt unwell, was examined by the medical officer of the Croydon workhouse, who pronounced him to be fit to leave, and referred him to the relieving officer for an order if he wished to enter the workhouse. Upon this Andrewes broke one of the windows, and was therefore charged by the workhouse authorities. He gave no reason for breaking the window, and did not complain of illness either to the police or to the magistrates. Consequently there was no reason for the police to obtain medical advice. On admission to prison he was found to be so ill-nourished that the assistant medical officer put him in the infirmary instead of on ordinary cell, but no actual illness could be observed until a day later.

Destruction of Vermin.—Mr. Cowan asked the President of the Local Government Board if he had received representations from the Scientific Committee of the Incorporated Society for the Destruction of Vermin and from other sources, urging immediate investigation as to whether the various bacteriological preparations now on the market for the destruction of rats were, or were likely to become, pathogenic to man; and what action the Board proposed to take in the matter. Mr. Burns replied that he did not find that the committee of this society had made any such representations as were above referred to, but his attention had been drawn to the question whether some action should be taken with regard to various bacteriological preparations for the destruction of rats, with a view to preventing danger to man, and the subject was now receiving consideration.

The Deaths Registration and Burials Bill, to amend the law relating to the registration of deaths and to burials, was presented and read a first time on Monday last. The bill is in charge of Mr. George Greenwood, and is backed by Sir Walter Foster, Mr. John Robertson, Mr. Smeaton, Dr. Rutherford, Mr. Hart-Davies, Dr. Shipman, and Mr. Atherley-Jones. It is down for second reading on March 9th.

Private Members' Bills are set down for Friday in each week, and the debate on the Address being finished, Mr. Pirrie was able to bring on his Scottish Temperance Bill last Friday. It is a moderate measure, and although vigorously criticized, passed its second reading by a large majority.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

BIRMINGHAM.

EPIDEMIC OF MEASLES.

THERE has been for some weeks past an epidemic of measles among the infants in the Birmingham schools. An inspection of the elementary schools shows that the number of children in the upper departments who are away through measles is small, but in the infant departments the number is very large, so that the Education Committee has found it desirable to close twelve of the schools. The deaths from measles during last week numbered 31, and in the previous week 25. The increased mortality from measles raised the total death-rate of the city to 20.8 per 1,000, as compared with an average rate of 15.9 for 1908.

RESULTS OF MEDICAL INSPECTION.

Dr. G. A. Auden, medical superintendent of the inspection of school children, has issued a report concerning the examinations made between September 1st and December 31st, 1908. The report covers only a portion of the school area. He explains that the prime object with regard to the statistical aspect of the work is to obtain data for the estimation of the present physique of the nation, which is a more complex problem than is apparent at first sight. During the four months covered by the report 10,000 children were examined, equivalent to a rate of about 30,000 a year. The Board of Education estimated that the inspection of the 96,000 children in Birmingham would take three years. A large number of the parents attended the inspections showing that they took a lively interest in the welfare of their children. Dr. Auden states that the nutrition of the Birmingham children compared very favourably with that of children in other parts. Out of the 10,000 children examined, 2,271 were found to have defects of one kind or another; 1,033 had affection of the eyes, and it was suggested that defective eyesight was largely manufactured in the infants' schools by allowing the children to place their books too near their eyes, the focal length of which being still variable became too short in consequence. The officers of the Dental Hospital have examined the teeth of 2,053 children, and report that only 4 per cent. were found to be dentally perfect.

The number of children already reported as suffering in some stage of pulmonary tuberculosis was 31, and in addition there were 39 in whom the symptoms were doubtful.

NEW MEDICAL MAGISTRATES.

Dr. Robert Simon, honorary physician to the General Hospital and consulting physician at the General Dispensary, and Mr. Gilbert Barling, honorary surgeon to the General Hospital and Dean of the Faculty of Medicine at Birmingham University, have been appointed by the Lord Chancellor to the Commission of the Peace for the City of Birmingham.

MANCHESTER AND DISTRICT.

MEDICAL INSPECTION AND TREATMENT OF SCHOOL CHILDREN.

Two points have come out very strongly in the recent discussions by the Manchester Divisions on the medical inspection and treatment of school children. In the first place, there is the determination loyally to support the decisions which the British Medical Association has already arrived at, first, in regard to the remuneration of whole-time and part-time medical inspectors, and secondly, in objecting to the subsidizing of hospitals for the sake of obtaining hospital treatment of children. In the second place, there is a practical unanimity in demanding that if there is to be any medical treatment at all at the expense of the rates, it must be strictly confined by something like a wage limit to those children whose parents are unable to pay ordinary fees; and further, that the surgeries of all practitioners who are willing to undertake the work should be recognized,

vouchers being given to the children to be taken to any such surgery that the parents may choose, and each voucher being paid for by the education authorities on a fixed scale. No attempt has been made to suggest what the wage limit should be, but it is demanded that, whatever may be fixed, it should not be allowed to become a dead letter. There seems to be a tendency in some quarters, mostly official, to regard the voucher plan as impracticable. It is said that the authorities would not be able to exercise sufficient control over a large number of practitioners, each to a certain extent independent, and that there would be no guarantee that cases would not be kept on longer than necessary in order to obtain the certain fees. This all amounts to saying that medical men cannot be trusted to do justice to patients. It seems to be forgotten that Manchester already offers a good example of this very scheme. A fee is already paid by the Corporation to any general practitioner who answers the call of a midwife, what amounts to a voucher being given to the doctor, which is paid for by the authority according to a fixed scale. The same objections as stated above were made to this when it was first proposed, but the plan has succeeded so well in Manchester that probably in no town in the kingdom has the Midwives Act been so successful, for parturient women are practically certain of obtaining medical aid with the minimum of delay, while the cost to the Corporation in 1907 only amounted to £247 10s. in medical fees. As for the other suggestion, that some doctors might be tempted unduly to prolong their treatment for the sake of the fees, it is practically certain that, putting the matter on the lowest grounds, no man with a grain of common sense would risk his professional reputation by any such dishonesty. But there is this further safeguard, that it may be presumed that the children would all the time remain subject to the periodical inspection of the official medical inspectors, who would readily detect any case in which treatment was unnecessarily prolonged. In addition to this it is noteworthy that the Majority Report of the Royal Commission on the Poor Laws actually recommends this plan for general adoption in all cases of illness in patients unable to pay fees. It even suggests that district medical officers may gradually be done away with. There is nothing that will so gain the confidence of the people as the knowledge that they can choose any doctor they wish. With that knowledge they will willingly submit their children to treatment when advised by the medical inspectors, whereas they would often absolutely refuse if they were bound to go either to someone whom they did not know or did not trust. The further suggestion of the Majority Report, that people who are not paupers but who are unable to pay ordinary fees should be induced to join provident dispensaries, would only slightly affect the voucher scheme for school children much later, as it would be a gradual process. Meantime if there is to be any treatment at all of school children at the public cost, the Manchester Divisions are in favour of vouchers that may be taken to any practitioner.

A FAMINE IN DOCTORS.

The *Manchester Evening Chronicle* is responsible for the statement that "a mild famine in doctors is threatened in the United Kingdom, as the number of students registered in the universities is seriously on the decline." It is said that the number of students registered in the three kingdoms in the year 1891 was 2,405. The course of study was then lengthened from four to five years, with the effect that in the following year only 1,671 names were registered. After that the figures slightly increased for a year or two, but soon again decreased, until in 1900 there were only 1,538 registered, and in 1907 the low water mark was reached of only 1,346. The writer professes to find in these declining figures an explanation of the fact that public bodies frequently obtain only a meagre response to their advertisements for candidates for vacancies on their medical staffs. It is somewhat curious to find that he quotes the experience of the Chorlton guardians, who recently had only five applicants for the vacant resident medical officership. He might have added the experience of the Salford guardians, who had only one applicant for a similar post. He seems to be ignorant of the fact that there may be other reasons for the fewness of applicants for such posts. The fact is that in the

Manchester district resident medical officers under boards of guardians are so badly paid, so much overworked, and subjected to so much interference by individual guardians that the posts are only taken at all *en passant* to gain some hospital experience. No one dreams of such posts as permanencies. On the other hand, when the salary and conditions are at all reasonable, there is usually an excessive number of candidates. For the medical officership at the Langho Epileptic Colony, where the salary offered was £250, in spite of the responsibility and the amount of work which is attached to the post, there were 54 candidates, while for the three medical inspectorships of school children for Manchester there were over 30 candidates. The *Medical Directory* for 1909 shows that, after allowing for deaths and the removal of names from the list for various causes, there was a total increase of registered practitioners of 289 over the previous year. The absurdly cheap club practice that is undertaken in Manchester would, one would have thought, have been sufficient proof that the profession is overstocked; but, even if it become doubly overstocked, it is not at all likely that boards of guardians will ever have an excess of candidates for their resident posts so long as the guardians remain what they are, and the conditions of service under them remain unaltered. It is far more likely that the guardians themselves will have disappeared long before there is a "famine of medical men."

NEWCASTLE-UPON-TYNE.

THE ROYAL VICTORIA INFIRMARY.

At the annual court of governors of the Royal Victoria Infirmary, held last week, the adoption of the annual report for 1908 was moved by the Lord Mayor of Newcastle-upon-Tyne and seconded by Sir George Hare Philipson. The infirmary is now in full swing, and gives accommodation to 425 patients. The expenditure for last year amounted to £30,892, while the income was £25,552, of which upwards of £14,000 was contributed by workmen's subscriptions. Taken on the total ordinary expenditure, the cost per in-patient was £4 1s. 10.2d., and the cost of per occupied bed £78 11s. 5d. Arrangements are in progress for a reorganization of the pathological department whereby the officer appointed shall give his whole time to pathology in the infirmary and the College of Medicine.

The interest of the annual court, which was attended by nearly 600 governors, centred round the chapel question. For the last twelve months the chapel, which had been consecrated, was closed for religious services in accordance with the decision of the last annual court. For many years past at these annual meetings the chair has been occupied by the chief magistrate of the city, and last Saturday afternoon it was filled by the Lord Mayor of Newcastle, who on his own initiative brought forward a scheme which he hoped would secure peace and remove discord. He suggested that a committee should be formed composed of four members chosen from the House Committee of the infirmary, four by the Workmen's Representatives, and four by the Free Church Council to confer with him as to the best means of settling a dispute which has given no satisfaction either to Nonconformists or Churchmen, and which has deprived the inmates of the infirmary of the opportunity of attending religious services in the institution. The Lord Mayor promised to bring the decision of this conference before a court of governors within three months. At one stage of the proceedings there were evidences of disagreement and of a considerable warmth of feeling, which was rather hostile than friendly to the proposal unless in some ways amended, but in the end good sense prevailed. Meanwhile, Dr. Hume, who all along has taken a keen interest in the matter, asked to be allowed to withdraw from the agenda a proposal standing in his name. It was thought that nothing would be lost by adopting the proposal of the Lord Mayor.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

The banquet of the Northumberland and Durham Medical Society, announced for March 18th, and at which Sir Lauder Brunton is to be the guest, promises to be very successful. Those who have not intimated their intention

to be present should do so at once to Dr. Wm. E. Hume, Royal Victoria Infirmary. An address will be given by Sir Lauder Brunton in the afternoon in the College of Medicine, and to it all medical practitioners are invited.

THE WEST STANLEY EXPLOSION.

At the adjourned inquest on the West Stanley Explosion interesting evidence was given by Drs. Benson and Charles, of Stanley, in regard to the 168 miners who were killed. Those killed by carbon monoxide numbered 121, those killed by direct violence 25, while 19 died from other causes. The explosion must have been very violent judging from the mangled and disfigured appearance presented by the dead bodies. In eight instances the head was terribly shattered, in a few cases being almost blown off.

SHEFFIELD.

EDINBURGH UNIVERSITY CLUB.

The fourth annual dinner of the Sheffield Edinburgh University Club was held on February 6th, under the presidency of Dr. H. J. Clarke, of Doncaster, and was attended by about 120 members and guests. Emeritus Professor Crum Brown was the guest representing the University of Edinburgh, the other two guests of the club being the President of the British Medical Association, Mr. Simeon Snell, and Dr. Sinclair White, who had been Local Honorary Secretary at the recent meeting of the Association.

Professor Crum Brown made an interesting speech reminiscent of old Edinburgh days, referring, among other matters, to his acquaintance with Syme, and touching also upon what was uppermost in the thoughts of many of those present, the recent death of Dr. Argyll Robertson.

Mr. Snell, replying as President of the British Medical Association, referred to his friendship with Dr. Argyll Robertson extending over many years. He mentioned that among many great kindnesses he had received at his hands was the manner in which he early stated his intention of leaving his retreat in Jersey to come to Sheffield to support him when President of the Association. This he accordingly did, and was one of the most prominent figures at the meeting; no one then could have thought that he would be so soon removed.

WEST YORKSHIRE.

PROPOSED REBUILDING OF THE ROYAL INFIRMARY, BRADFORD.

The annual meeting of the donors and subscribers to this hospital was held at the Town Hall, Bradford, on February 26th, the Lord Mayor presiding. There was a large attendance. The Chairman of the House Committee, in proposing the adoption of the report, pointed out that the work of the infirmary during the past year had been of an exceptional character. The number of in-patients treated was 2,652, whilst the highest number treated before in one year was 2,500. Five years ago the number was 250 less, and ten years ago 500 less. The increase had been largely in surgical cases. The average duration of residence had been twenty-six days in place of twenty-five, and the daily average number of patients had been 188—seven a day more than in 1907. The average cost per in-patient had been £4 2s. 7d. as compared with £4 6s. 4d. The infirmary was overcrowded and really required rebuilding. The Lord Mayor emphasized the urgent necessity for a new infirmary. It seemed to him that it would be impracticable to erect new buildings on the same site.

Dr. Horrocks pointed out that major operations in 1887 numbered 173; last year the number was 1,512, although the number of beds was exactly the same. For the past six or seven years there had been almost constant over-pressure. There was always a waiting list of patients, and patients had frequently to be sent home before their wounds were quite healed. Many chronic cases had to be refused and palliative treatment had frequently to be curtailed. He strongly objected to any proposal for municipalization of the hospitals. "Every one," he said, "who paid rates would be eligible for admission, and the pushing and energetic would soon occupy the beds to the exclusion of the poor and needy. The staff, instead of

being voluntary helpers, would become officials, and as there were thirty-two doctors, it would be necessary to reduce the number, as it would be impossible to pay so many of them adequately."

The Lord Mayor, in replying to a vote of thanks, said: "I think this meeting has pledged itself to a new infirmary, and hope that subscriptions will come in thick and fast." We believe that this is a wise decision, and hope it may soon be realized. The difficulty, of course, is in raising the necessary funds. Trade in Bradford is bad, and it will require extraordinary efforts to raise a sum of, perhaps, £150,000 to £200,000, which will be necessary adequately to equip and build a new hospital.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

STATE REGISTRATION OF NURSES.

A MEETING to consider the advisability of promoting a separate bill for the registration of nurses in Scotland was held in Glasgow on February 27th. Lord Inverclyde presided over a large assembly, which was thoroughly representative of the nursing profession throughout Scotland, and included delegates from many public bodies and institutions. The Chairman explained the genesis of the movement in favour of a separate bill for Scotland. The chief objections to the English bill from the point of view of the Scottish nurses were: (1) that the entire control of the training and registration of nurses in Scotland would be handed over to a council sitting in London on which Scotland had no direct representatives; (2) the fees suggested seemed unduly large—namely, 3 guineas for examination and 2 guineas for registration, especially in view of the fact that the examination was to be held only at centres which would necessarily entail additional outlay for travelling and hotel expenses; (3) the English bill required a nurse to undergo special examination for registration purposes no matter what certificate she might obtain from her teaching school; (4) it was felt that the examining body might possibly consist of individuals who had no direct interest in maintaining the high standard at present held in Scottish nursing. To meet these objections special legislation for Scotland seemed advisable: a bill had accordingly been drafted by a small committee, and had been sent to all nurses in Scotland. The meeting had been convened to determine whether the Scottish nursing profession approved of the general principles laid down. They differed from the English bill in several points. The central council was to be thoroughly representative of the various nursing branches and medical authorities. The fees for registration were to be much smaller and were to be kept as low as was compatible with meeting the working expenses. The examinations were to be held at the various teaching centres, and were to be left as far as possible in the hands of the training school, with supervision by the Registration Council to maintain an adequate standard. It was claimed that this draft bill more adequately represented the recommendations of the Select Committee which reported to Parliament in 1905 on the question of State registration. To determine the feeling of the nursing profession in Scotland, a plebiscite had been taken and the opinions recorded were overwhelmingly in favour of the draft bill. Dr. Mackintosh, who spoke next, stated that the plebiscite showed 2,718 were in favour of the establishment of a separate registration council north of the border. Thereafter a number of ladies and gentlemen representing various branches of the nursing profession spoke in favour of the draft bill. It was noticeable, however, that the mental representatives, who have already had several years' experience of the working of the medico-psychological examination, approved of the proposed bill subject to the condition that the standard adopted for mental did not fall below that of the medico-psychological certificate. At the close of the meeting a resolution was passed, almost unanimously, that Parliament be solicited to pass an Act for the registration of nurses in Scotland. An amendment received only seven votes.

PREVENTION OF EXCESSIVE INFANT MORTALITY.

The Anderson Health Association, at the time of its inception, aroused considerable opposition among local

practitioners. Some aspects of the scheme, however, were above criticism. Thus, with the view of reducing infant mortality, a bounty scheme, with systematic visitation, on the plan of the Huddersfield experiment, was started. The funds for this scheme were given anonymously, and it was started in January, 1907, and came to an end on December 31st, 1908. The streets selected were among the poorest of the district. In all 137 births were registered under the bounty system. To enable a proper comparison of the effects of the bounty system to be made, the medical officer of health furnished official statistics of the birth-rate and infant mortality in the streets selected for the experiment. The total number of births was 462, with 97 deaths, showing a mortality of 210 per 1,000. The death-rate among the registered children was only 138 per 1,000. The corrected mortality of unregistered children thus amounts to 240 per 1,000. The registration bounty scheme has, apparently, lowered the death-rate by 102 per 1,000. The interesting experiment of a bounty scheme, therefore, proved very satisfactory in practical working, as the mortality had been reduced nearly two-thirds in the particular streets selected for the experiment.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

DUBLIN HOSPITALS TUBERCULOSIS COMMITTEE.

SIR JOHN MOORE presided on Monday last at the first annual meeting of the Hospitals Tuberculosis Committee, when the report of the year's work was submitted. This committee looks after the outdoor patients reported by the hospital staffs, and sends nurses to attend upon those who require their services. In this way 274 families were visited during the year, and 7,087 visits were paid; 35 per cent. of the patients had shown distinct signs of improvement, 10 per cent. had been able to resume their ordinary work, 81 persons had been admitted to sanatoriums, 110 rooms had been disinfected. Nutritious food had been supplied to 106 families.

IRISH IN THE NATIONAL UNIVERSITY.

The Gaelic League is not quite satisfied with the prospect of inducing the Senate of the National University to make Irish compulsory for entrance. It is known that many of the stronger members regard such a rule as dangerous to the future of the institution, and will vote against it. The Bishops have not altered their opinion, and so it is most probable that when the proposal comes up for decision, in some months, it will be defeated. The league, small as it is, is active, and it is now calling upon the various district and county councils to refuse to levy any tax for scholarships unless their demand in reference to Irish is granted. The Dublin Corporation and a large number of councils throughout the country have come to this decision, in the hope that the Senate may be starved into acquiescence.

TYPHOID FEVER IN DUBLIN.

In the autumn of 1908 there was an outbreak of typhoid fever in the Clontarf district of Dublin, where there is a population of some 5,000 persons. In a special report, which has just been issued, Sir Charles A. Cameron describes certain characteristic features of the outbreak, which point to a milk-borne origin. He was unable, however, to place his hand on the person by whom the infection was started. This being so, a difficulty arose as to what action could be taken with respect to the sale of milk from the suspected premises. In the absence of any knowledge of disease in connexion with any one in the dairy, the law agent of the Dublin Corporation was of opinion that the provisions of Section 4 of the Infectious Disease (Prevention) Act, 1890, could not be enforced, and this opinion was endorsed by Mr. Ignatius O'Brien, K.C. On the other hand, Mr. Vanson, K.C., the law adviser of the Irish Local Government Board, expressed a very decided opinion that the section was capable of being very widely construed, and he apparently considered that the Corporation possessed the power to stop the distribution of milk from the dairy in question. In the course of his investigations as to the cause of the outbreak, Sir Charles Cameron was on the alert for possible carrier cases, and he induced the proprietor of the dairy to submit

to bacteriological examination the excretions of the persons connected with the dairy. It is to be regretted that the results of these examinations have not been made public, though the responsibility for this does not lie with Sir Charles, who appears to have dealt with the outbreak in a thorough and vigorous manner.

THE MEDICAL CURRICULUM.

The Ontario Medical Council has decided that a two months course in electro-therapeutics shall be added to the requirements of the curriculum for admission to practice, and that in examination questions no proper names be used to designate diseases.

THE MEDICAL FACULTY, TORONTO UNIVERSITY.

Dr. C. K. Clarke, of the Toronto Hospital for the Insane, has been appointed Dean of the Medical Faculty of the University of Toronto in place of Dr. R. A. Reeve, who resigned after twelve years of arduous service.

THE NATIONAL SANATORIUM ASSOCIATION.

The trustees of the National Sanatorium Association have appointed Dr. Alfred H. Canfield, who was trained in the laboratory of Sir Almroth Wright and who has been recently resident pathologist to the Toronto General Hospital, as resident pathologist to the Muskoka Sanatorium and Free Hospital for Consumptives, where he will give all his time to the study of the problems of this disease.

BERLIN.

Compulsory Vaccination.—Statistics of the Charité Hospital.—Rules for Hospital Administration.—A Tuberculosis Charity Kitchen.

AN important decision, bearing on the question of compulsory vaccination, has been given by the Prussian High Court of Administrative Law (*Ober-verwaltungs Gericht*). The facts of the case are shortly as follows: A number of Magdeburg mechanics had failed to present their children for vaccination at the age and within the limits of time stipulated by the Prussian Vaccination Act, and had been fined accordingly. Three years having elapsed without the children being vaccinated, the President of the District (*Landrath*) ordered the fathers to comply with the law without further delay, or the children would be forcibly vaccinated. Against this order the fathers lodged a remonstrance, setting forth that they had conscientious objection to vaccination as injurious to the constitution, and arguing that the Act, though it speaks of a fine to be inflicted in cases of non-compliance, nowhere makes mention of a power to enforce vaccination against the will of parents. The remonstrance was dismissed, and an appeal to the Supreme Court of Administrative Law met the same fate. The court based its verdict on the words of the Act, that—except in certain individual cases, where it would be fraught with danger to life and health—all Prussian children must submit to vaccination.

A set of very detailed, and therefore valuable, statistics have been published by the Charité State Hospital for the year 1906-7. The year began with 1,177 patients in the wards, and 14,485 more were received during the twelve months; 2,543 children were born in the hospital, and counting these, 13,889 persons were dismissed in good health or cured; 1,863 persons were dismissed uncured, 1,382 died. The 15,596 patients required 421,778 days of treatment, that is, the average was 27 days' stay in hospital per head; 9,855 days were gratis, 256,804 days were at the charge of the Berlin Municipality, 115,119 days at the charge of sick clubs and similar institutions. The medical staff consisted of 13 medical and surgical directors or chiefs, all of them Professors in the University, 55 medical and surgical heads of departments, head physicians and surgeons, and assistant physicians and surgeons—among these 20 military surgeons and 1 female doctor; 82 Sisters, 4 midwives,

96 male and 115 female nurses; 4 wet nurses had charge of the patients, and were assisted by 34 male servants and 25 housemaids; 19 men composed the service of the laboratories. The administrative staff consisted of a head medical and a head managing director, a professional lawyer, 25 cashiers and office clerks, 3 clerks for the food department, 4 clergymen, an organist, 4 druggists, 18 subordinate clerks, 146 mechanics and men servants, and 109 female servants.

For some time the Prussian Cultusminister has been occupied with plans for putting the medical direction of hospitals on a uniform basis. After consultation with the Representative Body of Doctors (*Ärztelkammer*) and its Central Committee, certain fundamental rules have been worked out and officially published. At the head of every institution for care of the sick there is to be a responsible medical administrator of independent powers who superintends both the general care of the patients and all hygienic arrangements. All larger hospitals—counting as such establishments with more than thirty beds—must have further a doctor-in-chief, responsible for the treatment of each patient, or head doctors or head surgeons for the various departments. This is to be interpreted without prejudice to specialists, who may be doing work in the hospital. In lesser public hospitals, especially in small towns, and likewise in private hospitals, sanatoriums, and private nursing homes, etc., outside doctors are to be allowed to treat patients of their own, or may assist the hospital doctors, always under the sanction and responsibility of the head medical administrator. The Cultusminister defines as "public" all hospitals or institutions for the sick worked without special concession.

It must have been gratifying to Frau vom Rath, a charitable Berlin lady of great experience and ability, to receive Robert Koch in her "model kitchen for supplying the tuberculous poor with strengthening meals," since this institution was founded and endowed solely by her without any appeal for subscriptions, and its work is carried on under her constant personal supervision. No less than 180 units—families and single persons—are supplied from this kitchen daily, at a cost of 40,000 marks (£2,000) per annum. Frau vom Rath keeps to a strict rule, which excludes from the benefits of the charity all who do not use their best endeavours to keep their homes clean and hygienic. Thus, and thus only, can she hope to do more than benefit single cases of the disease. Professor Koch inspected all the rooms of the establishment, examined in detail all the arrangements, and informed himself of the kinds of food provided and their mode of preparation, the transport appliances, and so forth. Everything he found so carefully and thoughtfully planned, and so conscientiously executed, that he could only express his warmest admiration, and his conviction that the "tuberculosis charity kitchen" would form a valuable weapon in the fight against the terrible scourge.

Correspondence.

THE POOR LAW COMMISSION.

SIR,—Your second admirable article dealing with the report of the Royal Commission on the Poor Law deserves more than passing attention. It brings out what the Minority Report has startlingly emphasized—namely, the exceedingly high infant mortality that prevails among the children committed to the care of the Poor Law institutions of the United Kingdom. If these figures are correct, then the death-rate is two or three times as high for Poor Law babies as it is for the rest of the infant population of the country. That there is something radically wrong in the way in which infants are dealt with in these institutions is shown by the unwholesome diet, the absence of the means for rest, air, and exercise, which were personally observed and recorded by members of the Royal Commission. If further evidence were needed, there is condemnation enough in the facts that legitimate and illegitimate birth-rates are about equal and that the mortality is actually higher between the end of the first month and the sixth month than in the first four weeks of life.

We see at the present time that, in order to combat the existing widespread physical unfitness of the population, public health authorities are making special efforts by

means of health visitors, infant milk dépôts, and the early registration of births to reduce the general infant mortality rate, whose height is a fairly good index of the health condition of the population generally. At the same time another department, staffed by officials paid out of public funds, and actually under the supervision of the Local Government Board itself, is responsible for a condition of things that is literally characteristic of the worst slum areas of the great towns!

We have here something more than an instance of the absurd overlapping of functions of two departments of local government. It is a clear demonstration of the fact that the proper authority to take charge of pauper infants is surely that to which the care of the general infant population is at present entrusted, namely, the Public Health Authority—the body whose knowledge and interest lie in the direction of taking special precautions to preserve life. At the present time one authority is spending money and time to reduce the infant death-rate while another is keeping it at a level which, if it occurred in an ordinary urban district, would result in an official inquiry by a medical inspector of the Local Government Board.

It is imperative, then, that in order to set the public mind at rest a searching official inquiry should at once be instituted into the question of the infantile mortality in all Poor Law institutions, and a report made on the general conditions of life in so far as they affect the destitute child population of the kingdom. We must know to what extent the figures of the Minority Report represent the prevalent conditions in workhouses. The burden of the present highly unsatisfactory system for the relief of the poor appears to be falling with peculiarly cruel severity on those who at least can claim no responsibility for their unhappy condition.—I am, etc.,

London, W., Feb. 28th.

F. LAWSON DODD.

FRIENDLY SOCIETIES AND THE MEDICAL PROFESSION.

SIR,—We must all be grateful to Dr. Pearce for his admirable speech at the conference, covering every point, extenuating nothing, setting down nought in malice, so admirable as almost to debar criticism or suggestion. Yet, since he declined to offer a solution, may I suggest that the solution will be found in the operation of the economic law of supply and demand?

Dr. Pearce said "he was persuaded that if nothing were done, an increasing number [of medical men] would decline to have part or lot in contract practice." I suggest that this opinion is unwarrantably optimistic, and that the friendly societies know as well as we do ourselves that whatever remuneration they offer, they will never lack competent doctors. As Mr. Moffrey (Oddfellows) said later: "A friendly society's practice was perhaps as important to the medical man as it was to the society . . . though it might be a mere pittance, the societies found that when a vacancy occurred others were ready to step in and carry on the work."

There is no doubt that the latter statement is correct, and if so the societies' position is unassailable: as long as there are more sellers in the market than buyers, prices must fall; that there is an excess of sellers who can doubt? In Bristol the other day for the school medical officerships thirty-seven of the best men in the city applied, and there were appointed two hospital physicians and three others at a salary 30 per cent. below the minimum fixed by our Association. A year ago the guardians received and accepted from a qualified man an offer to attend pauper children at 6d. a visit. The manager of a factory to which I am medical officer told me that at the time my predecessor sold me his practice another doctor (whom he named), hearing of the change of incumbent, actually applied at the factory to take on the penny-a-week sick club which formed part of the practice I had paid for.

What is the remedy, and where does the law of supply and demand come in? I submit that we accept contract work because there are too many of us, and that supply is here in excess of demand simply because of ignorance among the public as to what the practice of medicine offers as a livelihood. The middle and upper class public knows nothing of the general practitioner's financial worries; it judges the profession by the carriages of its own particular medical advisers, and does not realize that the

majority of doctors get their living by services rendered to the majority of the nation—the very poor. The teachers at our universities and colleges have never a word of warning for their students as to their prospects after qualification, and, as Dr. Pearce says, "many a man who began his work with enthusiasm finds his professional life embittered by the evils of the contract system, which blights his hopes, stifles his ambition, and destroys his love of work."

The contract system is far more extensive than any one has publicly remarked; in this large town there is hardly a factory without a sick club and medical officer, and from half to three-quarters of the population must get medical attendance in this way or through hospitals and dispensaries.

The remedy is to cut down the supply of doctors, and this can only be effected by being frank about our affairs. Give the public a sight of the annual report of our benevolent fund, with its pitiful list of widows and orphans needing assistance; let them note, also, the paltry doles of £1 a month, which is all we survivors can afford from our own precarious incomes: it could not fail. I should think, to affect adversely the matriculation of medical students at our schools next term. With the thinning of our ranks, our hands will be untied to carry on this "battle of the clubs" with success, and with a better income and freedom from worry, I am sure we most of us would be better doctors. I have always thought that medical practice demanded undivided thought, and that any worry, financial or otherwise, militated against my patients receiving the attention I desired to give them.—I am, etc.,

ECONOMIST.

PATENT MEDICINE AND QUACKERY.

SIR,—On February 25th the Home Secretary favourably received a deputation of newspaper editors and proprietors on the subject of newspaper lotteries and competitions, and promised to do his best to introduce legislation to provide a satisfactory remedy. If the Government can provide legislation to prevent foolish people throwing away their money, how much more should it promote legislation to prevent a still greater proportion of fools losing not only their health but even lives by the ingestion annually of hundreds of thousands of pounds' worth of patent medicines!

Only a few days ago a jury in Manchester, according to a Manchester evening paper, after being absent about twenty minutes, "found that the life of the deceased was shortened by his taking Dill's mixture (a diabetic 'cure'), and by his not continuing on the advice received from his Nottingham doctor."

The remarks of the Home Secretary relatively to newspaper competitions might have been truly spoken with regard to this subject: "These . . . were sometimes harmless. They were rarely useful, frequently mischievous, and not infrequently fraudulent. Taken on the whole, they were degrading to all concerned." Those who have read the reports of your analyses of secret compositions could vouch for the accuracy of these words as applied to them.

As you have previously pointed out, other countries—for example, Australia and Germany—are providing the necessary legislation to get as near as possible to the root of this canker. Would not this be a favourable opportunity for a deputation from the Association to approach the Government with regard to the whole question, the newspaper precedent acting as a lever should any hitch occur? The evidence at the disposal of such a deputation would surely be convincing enough for any Government to make a move.

The day on which the newspaper deputation account was printed I wrote on the subject to one of the London dailies which seemingly can move mountains with a stroke of the pen; but the letter has been ignored, probably because it was stated that, until the Government did certain things, "just so long will this great gullible public, which urgently requires State protection, swallow the rubbish, as it does the barefaced, lying assertions printed for its benefit (!) in the advertisement columns of every newspaper."—I am, etc.,

Manchester, March 1st.

G. H. GRANT DAVIE.

THE APPLICATION OF MENDELIAN RULES TO HUMAN INHERITANCE.

SIR,—Professor Karl Pearson, in his last letter, gives way on the two points under discussion, but again shoots off at a tangent more than once.

The essential points in dispute, as I have already explained—and I think clearly explained—are two, both concerning Nettleship's chart. I have divided it into two parts. The first begins with Jean Nougaret, and includes all the abnormals; the second part begins after the last abnormals.

The first part, I contend, is Mendelian—almost mathematically so—and could not be interpreted otherwise. Professor Pearson says that he does "not feel in a position to say what Mendelians would have considered" about it. Yet it seems to me so striking an example of Mendel's law that it might have been quite as suggestive to Mendel as were his results with peas, for even with peas he seldom, if ever, got the exact 50 per cent. required by his theory, the element of chance accounting satisfactorily for any discrepancy.

With regard to Professor Pearson's reference to assumed sterility of the last abnormals not being in accord with any known law of Mendel, I am not aware that any one has ever said it was. Certainly this idea has never been assumed in my previous correspondence. Professor Pearson surely can think of other ways by which the same result would be attained (by celibacy, prudential considerations, early deaths). But this matter does not concern the points in dispute.

The second point is that some new factor must have come into operation where Mendel's rule begins to be inapplicable. Professor Pearson says "he does not quarrel with the statement"; and this is surely a complete surrender. So that the net result is this: (1) He does not know what Mendelians would think about the first part of the chart; and (2) he does not quarrel with my interpretation of the second part.

How he can reconcile his applying, in his earlier letters, such caustic epithets to my suggested explanation of the second part of Nettleship's chart with his present surrender I cannot imagine; unless it be that he at last understands my views and sees their reasonableness. But Professor Pearson goes further, and says: "There will, I feel quite certain, be other difficulties to be cleared up about change of dominance." Here he explicitly admits that change of dominance is a definite factor, in spite of his previous ridicule of such an idea.

There is one more point on which I must put Professor Pearson right. It is Professor Cossar Ewart and Professor J. A. Thomson who seem to believe that prepotency may change in the mating. For my part I do not believe that it occurs in man, for I am not aware of any facts in man which support that view, though I certainly believe that prepotency may change with a change of mate, that is, it is relative.

There is one point, I am pleased to say, about which we are agreed, and that is the urgent need for the collection and publication of facts bearing on this subject. No one in this country has been more enthusiastic and diligent in this respect than Professor Pearson, and I would earnestly ask medical men to embrace every opportunity of constructing charts of hereditary disease or abnormality in the human subject, and to make their observations accessible to the profession at large.—I am, etc.,

Wrexham, March 1st.

H. DRINKWATER.

MR. GLADSTONE'S SLEEPLESSNESS.

SIR,—In his very interesting paper, *On Sleep and Want of Sleep* (BRITISH MEDICAL JOURNAL, February 27th), the Right Hon. Dr. R. Farquharson states:

"They say that the only time Gladstone went off his sleep was during his anxiety for Gordon during that anxious time at Khartoum."

That there has been at least one other cause which during his political career robbed him of his sleep I have heard from Mr. Gladstone's own lips. When I saw him on February 2nd, 1886, the day he had begun to form his third Administration, I found him very haggard and careworn looking. On my remarking that he seemed rather tired, he replied *verbatim*: "That Irish business does not let me sleep a single night."—I am, etc.,

London, W., March 1st.

FELIX SEMON.

ARTERIAL BLOOD-PRESSURE RECORDS BEFORE AND AFTER MUSCULAR EXERTION.

SIR,—If I understand correctly Dr. O. K. Williamson's remarks on arterial blood pressure, in the JOURNAL of February 27th, p. 530, he regards 160 to 170 mm. Hg as "the measurement which is probably near the limit of the reserve power of the normal heart," pointing to "the improbability that the heart in morbid conditions would be capable of overcoming pressures greater than this"; and therefore very high readings—200 to 300 mm. Hg—represent something more than the pressure of the blood itself.

Of course, I quite agree with Dr. Williamson that the resistance of the arterial wall must count for something, but I cannot follow him when he assumes that the heart in morbid conditions cannot overcome greater pressure than a normal heart.

In the *post-mortem* room it is not an uncommon thing to find in cases of arterio-sclerosis a greatly hypertrophied heart, the muscle of which is healthy both macroscopically and microscopically, and surely such a heart is capable of overcoming pressures much greater than normal; is it not, indeed, probable that the great hypertrophy of its left ventricle has been brought about by the demand for increased blood pressure, a pressure greater than that which a heart of normal size could produce?—I am, etc.,

Birmingham, Feb. 28th.

LEONARD G. J. MACKEY.

USE AND ABUSE OF ALCOHOL.

SIR,—In correction of the statement attributed to me on page 535, BRITISH MEDICAL JOURNAL, February 27th, that alcoholism was responsible for the diminishing birth-rate, I beg to point out that, in reply to one of the speakers who made that statement, I said that it might be one of the factors producing such a result, but that it must not be forgotten, as taught by Herbert Spencer, that genesis varies with individuation, and that the higher and more complex the organism the lower the rate of increase—savages breeding more freely than civilized people, and even amongst the latter it was the lower classes that had the most children.—I am, etc.,

G. T. COLLINGWOOD,
Fleet Surgeon, R.N.

London, S.W., Feb. 27th.

THE MEDICAL ASPECT OF DENTISTRY.

SIR,—My attention has been drawn to a statement in Professor Pickerill's most interesting and instructive article in the issue of February 13th to the effect that "Dr. Dauber, of the Hospital for Women, Soho, has recently come to the conclusion that septic teeth have a distinct influence upon uterine and ovarian conditions, and gives many instances in which the gynaecological lesion has only yielded to treatment after the oral conditions have been corrected."

My lecture, "Oral Sepsis and its Relation to Abdominal Disease," to which Professor Pickerill refers, was reported in *The Hospital* of February 8th, 1908, and reprinted in the *British Dental Journal* of April 1st, 1908, and there is no single sentence in it conveying this meaning. My actual words were these:

Strictly as one may attempt to limit cases coming here (the Hospital for Women, Soho) to those of purely gynaecological interest, yet patients are unable to diagnose their own complaints. A certain percentage attend who, either in conjunction with or apart from pelvic mischief, are suffering from conditions attributable to deficient nutrition, general septic absorption, toxæmia, or some form of inflammation or colic of one or other portion of the alimentary canal.

I then proceeded to demonstrate the frequent association of such cases with oral sepsis in one form or another, and said that:

My own out-patient experience leads me to believe that, if the mouths and teeth of the population were kept in a healthy state, we should seldom hear of gastric and duodenal ulcer, and the entire large class of dyspepsias. There would be far less malnutrition and emaciation resulting from toxæmia and the ingestion of insufficiently masticated food. Appendicitis would be less frequent, etc.

To associate diseased conditions of the digestive tract or constitutional sequelæ secondary to such conditions with sepsis of the oral cavity, itself the first part of the alimentary canal, is a very different matter to attributing uterine and ovarian disease to oral sepsis. The connexion

in the latter case must be very remote, and, except that all parts of the organism are inter-connected through the vascular and nervous systems, may, I think, be safely disregarded.

My point was that the uterus and its adnexa were often credited with being the cause of many complaints when, in truth, they were healthy, but the abdominal viscera at fault, and that these latter were thrown out of gear in the majority of cases by unhealthy conditions in the mouth. Professor Pickerrill, although he quotes my lecture, cannot have read it, and as his article deserves to be, and doubtless will be, widely read, I desire to correct his interpretation of my remarks.—I am, etc.,

London, W., Feb. 26th.

JOHN H. DAUBER.

TREATMENT OF RHEUMATIC AND RHEUMATOID ARTHRITIS BY RADIANT HEAT AND CATAPHORESIS.

Sir,—Dr. Gamblen raises a very interesting point *re* ultra-violet rays in his letter (p. 371), although it does not affect the view that better results in radiant heat treatment should be obtained by a very high candle-power lamp giving out a full-length spectrum (as like sunlight as possible), than from a number of low candle-power lamps with a limited spectrum. With this opinion his practical experience agrees.

The general belief with regard to all rays is that they are not at once abolished in passing through obstructive media, but are altered into rays of other wave lengths as they pass. It is possible, therefore, that, although ultra-violet rays may lose their distinctive character in the superficial layers of the skin, they may nevertheless pass on into the deeper tissues as other rays, which may be the real beneficial agents.

The blue fluorescence of quinine sulphate solution beyond the violet end of the spectrum is a case of change of wavelength. It has also been stated that although the ultra-violet rays when used alone only act superficially, they are in combination with other rays carried to greater depth.

Certainly chemical rays producing an effect on silver emulsion of a photographic plate must either have started from the sun as chemical rays, and been unaffected by their passage through great resistance, including the photographer's glass lens, or they began as other rays which have been gradually damped down until they arrive at the plate as chemical rays, and act upon it.

It is gratifying to hear that Dr. Gamblen has had many successes in the treatment by ionization, and I hope with him that other workers will send their opinions as to the value of the combined treatment.—I am, etc.,

Brighton, Feb. 7th.

C. FRED. BAILEY.

Public Health

AND

POOR-LAW MEDICAL SERVICES.

INFANTILE MORTALITY IN WANDSWORTH.

IN the annual report for 1907 of the medical officer of health for Wandsworth, which has just been issued, Dr. Caldwell Smith points with satisfaction to the decrease in the deaths among young children in the whole borough. The infantile mortality-rate of 101 per 1,000 births was lower than any rate ever yet recorded, though, as might be expected, in the poorer district of Tooting the rate (148) is still high, and shows little evidence of decrease. This lessened mortality is attributed partly to the low average temperature in July, August, and September, but it must also be due to the work which has been carried out since 1905 by the two female sanitary inspectors. In 1907 they visited altogether 1,603 infants, of whom it is satisfactory to find as many as 1,255 were breast-fed entirely, and 174 were fed on the breast together with some other food. The death-rate among these 1,603 children was only 30 per 1,000, an excellent record when it is remembered that they are the children of the poor. Illegitimate children in Wandsworth, as elsewhere, have a much smaller chance of surviving their first year than children who are born in wedlock. In the whole borough the infantile mortality-rate among legitimate children was 97 per 1,000, while among illegitimate it was 236. It is worthy of remark that in the poor district of Tooting the illegitimate rate was 290, but in Clapham, where a better class of residents is to be found, it was as high as 331 per 1,000.

HEALTH OF LANCASHIRE.

THE medical officer of health for the county of Lancashire reports that the death-rate for the administrative county for the quarter ending December 31st, 1908, was 14.4 per 1,000, as compared with 13.9 in the December quarter of 1907. The epidemic death-rate, excluding diarrhoea, was 0.86 per 1,000, which is slightly lower than last year. There have been no cases of small-pox, but scarlatina, diphtheria, enteric fever, and measles have each had a greater prevalence than in the preceding quarter. Measles especially has been very prevalent, the schools having had to be closed in no less than fourteen districts. In some districts as much as 58 per cent. of the children in infant schools have had the disease, and in many other places from 35 to 50 per cent. have been attacked. A special report has been found necessary on the extensive outbreak of enteric fever at Tyldesley and Atherton. At neither place has any fault been found with the milk supply. At Tyldesley, up to the date of the report (November 23rd), 54 cases had been notified with 8 deaths. In 10 cases there was a history of eating mussels or oysters. Some suspicion fell on the water supply, which is obtained from the Manchester Corporation, and three samples were submitted to Sir Robert Boyce of the Liverpool University. In each case the *Bacillus coli* was found in 10 c.c.m. but was absent in 1 c.c.m. At Atherton, between January 1st and October 13th, only 8 cases had occurred, but from October 19th to the end of the year 34 cases occurred with 7 deaths. In 13 cases the sufferers had partaken of mussels. The medical officer of health for Atherton says that the water supply, though not good, cannot be held responsible. In one sample the *Bacillus coli* was present in 50 c.c.m. but not in 40 c.c.m., while in another it was present in 40 c.c.m. but absent in 30 c.c.m. The coincidence of this outbreak with a similar one in Salford, which is ten miles away but receives the same water supply, ought to lead to a careful examination of the water coming from Thirlmere.

SETTLE DISTRICT INFECTIOUS HOSPITAL.

THE new Infectious Diseases Hospital erected by the Settle Rural District Council at Harden Bridge, near Clapham, was formally opened on February 15th. The hospital has cost £5,680, exclusive of the cost of site and furnishing. It comprises a commodious administration block, with matron's rooms and premises for a caretaker, a scarlet-fever block with accommodation for 14 patients; a double isolation block for 6 patients, so arranged that diphtheria or enteric cases may be dealt with at the same time; and laundry, disinfecting chamber, and mortuary.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Chelmsford Rural District.—Calculated on an estimated population of 20,650 persons, the birth-rate in 1908 was 23.9 per 1,000 and the death-rate 13.9. The infantile mortality-rate was equal to 69 per 1,000 births. Dr. Thresh states that although medical practitioners in the district were asked several years ago to notify to him cases of pulmonary tuberculosis occurring in their practices, he had only been notified of one or two. In the grounds of the union workhouse three tents have been provided and are occupied by patients suffering from tuberculosis, who are said to do well under these conditions. Dr. Thresh suggests that additional shelters should be erected. There were nineteen deaths from phthisis in the Chelmsford rural district in 1908.

DUTIES OF WORKHOUSE SURGEONS.

C. E. D. asks whether the extraction of teeth comes under the heading of surgical operations in an agreement with guardians as medical officer to workhouse?

* * Unless there is some special agreement with guardians which relieves the medical officer of a workhouse of this responsibility, he is expected to provide the *requisite treatment* for all dental cases.

MEDICAL CERTIFICATION OF WORKHOUSE LUNATICS.

R. R. A. asks: What is the recognized practice in union workhouses in reference to the certification of lunatics? Also, whether it is a professional or friendly act of a medical practitioner to enter a workhouse to certify patients at the request of a magistrate? Our correspondent adds that for fifteen years past the magistrates have employed the medical officers of the workhouse for this duty, but lately a new magistrate has changed the system.

* * The practice varies very much. We cannot regard it as a breach of professional etiquette for any medical practitioner to visit a workhouse to certify lunacy cases if requested to do so by the magistrate who is acting in the case, as many magistrates for their own protection prefer to call to their assistance a medical practitioner in whom they themselves have confidence. Notwithstanding this, we should regard it as unfriendly action for any medical practitioner to bring about any such change of system as that described by our correspondent by *soliciting* engagements for these special duties.

Obituary.

DAVID JAMES HAMILTON, LL.D., M.B., F.R.S.,

EMERITUS PROFESSOR OF PATHOLOGY IN THE UNIVERSITY
OF ABERDEEN.

The death of Dr. David James Hamilton, formerly Professor of Pathology in Aberdeen University, will occasion deep regret to a wide circle of former students and friends. As briefly stated in last week's issue, he died at his residence, Queen's Road, Aberdeen, on February 19th, after an illness extending over a period of nine months. From the first there was no hope of recovery, and at the comparatively early age of 60 years the science which he adorned has lost one of its most brilliant exponents and investigators.

David James Hamilton was a native of Falkirk, and

studied medicine at Edinburgh University. After graduating he became a House-Surgeon of the Edinburgh Royal Infirmary, and subsequently held the post of Resident Medical Officer to the Chalmers Hospital in that city. At a later period he was elected Resident Physician and afterwards Resident Surgeon to the Liverpool Northern Hospital. His tenure of these offices extended over a period of two years, and during that time he had full control of the pathological department of the hospital. Pathology had a strong fascination for him, and it was then he decided to devote his whole energy to it. It is said that some of his medical friends tried to dissuade him from this course, being doubtful of the wisdom of his attempting to carve a successful career in a subject which at that time held a minor position in the medical curriculum. The reply was characteristic of the man: "If I can I will, and if I will I can," and his whole career was a justification of the confidence he placed in his own judgement. His special aptitude for the science of pathology

was recognized by the medical staff of Guy's Hospital, who awarded him the Triennial Astley Cooper Prize of £300 for his pathological researches on the diseases and injuries of the spinal cord—a prize open for competition to the whole profession. Two years were afterwards spent in visiting and working in the pathological departments of some of the best Continental schools, including those of Vienna, Munich, Strassburg, and Paris.

He returned to Edinburgh, and was appointed Administrator of Pathology in the University, and under the direction of the late Professor Sanders he organized a course of practical pathology, and gave much more prominence to the teaching of that subject than had hitherto been accorded to it. He was also appointed Pathologist to the Edinburgh Royal Infirmary, and on the death of Professor Sanders he was selected to fill a similar post at the Royal Hospital for Sick Children. During Professor Sanders's illness, Dr. Hamilton, at the beginning of the winter session 1880-81, was chosen to

deliver the lecture in General Pathology in the university, and he also organized a class of morbid anatomy and pathological histology in the School of Medicine similar to that which he had previously conducted in the university.

In 1882 came his appointment to the Chair of Pathology, which had just been founded by Sir Erasmus Wilson, in the University of Aberdeen. The task he undertook was no light one, but it gave him a great opportunity, of which he took full advantage. During the twenty-six years of his connexion with Aberdeen University he attained an outstanding position in the pathological world and won honour for himself and for the university. He organized and equipped the Department of Pathology both in the university and in the infirmary in such a manner as to make it a credit to both, and his conduct of the department on all its sides put the Aberdeen school of pathology in a leading position in this country. In the

practical application of his subject to public health he was deeply interested, and he brought into use in the North of Scotland the bacteriological diagnosis of diphtheria and typhoid fever, and the examination of water by bacteriological methods. For many years his *Textbook of Pathology* has been regarded as a most valuable work. His powers as a teacher gave him a unique position, and there was perhaps no one in this country who had so many pupils occupying important positions all over the world as teachers of pathology and scientific investigators. In a university which is fortunate in the possession of many distinguished lecturers Dr. Hamilton occupied a foremost position. His lectures were models of scientific exposition, delivered in a most fascinating and lucid style, with an accuracy of phrase and happiness of simile that could not be surpassed. He constantly kept before his pupils the value of experimental methods, and instilled into them some, at least, of his own thoroughness; by his lucidity and vigour and singular

DAVID JAMES HAMILTON.

individuality of character he had the faculty of arousing and sustaining the interest of his students and of inspiring them with his own enthusiasm. He did not believe in the ordinary set lectures, and latterly his course consisted of a series of demonstrations, during which he walked about. He made much use of chalk diagrams, many of them beautifully drawn in pastel, and of large models of such things as karyokinesis and other cell processes. There is no figure of an old teacher that the Aberdeen student can recall with greater accuracy than that of Hamilton in his daily march behind the rostrum in the lecture theatre, or in the practical laboratory or *post-mortem* room.

As to his many and notable contributions to the literature of medicine and science, it was said by the Dean of the Faculty, when presenting him for laureation as LL.D. in Edinburgh in 1907, that "the textbooks he had published, based as they are on data gathered through long years of study and observation, and reflecting, as they do,

the workings of a keen, unprejudiced, and independent intellect, deservedly enjoy a high reputation as illuminating and authoritative works." For two years he dealt with the pathology of bronchitis, catarrhal pneumonia, tubercle and allied diseases in the human being, in a monthly series of articles appearing in the *Practitioner*. He also conducted extensive investigations in connexion with the working out of the topography of the brain in relation to disease, the expenses being defrayed by a grant from the Royal Society of London. Dr. Hamilton was Morison Lecturer for 1882 of the Royal College of Physicians, and took as his subject the recent pathology of the central nervous system. To agricultural science Professor Hamilton had rendered services of inestimable value. He was indeed a tireless investigator in a wide range of subjects. Pleuropneumonia, tuberculosis, and other diseases which affect cattle were investigated by him, but

his reputation in that direction was earned in connexion with the discovery of the bacillus of "loupin' ill" in sheep. In the year 1881 he acted as chairman of a commission appointed by the Highland and Agricultural Society to make pathological inquiry into that disease and braxy. In 1897 he resumed the study of braxy privately, and subsequently received a grant from the Government for the purpose of carrying on his investigations. From an early stage good hopes of a successful termination of the researches were entertained, and in view of the truly national character and great importance of the work the Highland and Agricultural Society suggested that the inquiry should be taken in hand by the Board of Agriculture, and prosecuted to the fullest extent under the direction of Professor Hamilton. This was agreed to, and in 1901 he was appointed Chairman of a Departmental Committee, which presented its report in 1906. One result of these investigations was to establish Dr. Hamilton's discovery of the bacillus of "loupin' ill," the cause of which had not been known prior to 1901. The bacterial character of "braxy" was also established by him by researches, which confirmed the discovery of the specific bacillus by Ivan Nielsen in Norway in 1888. Another most important and interesting scientific inquiry with which he was also identified was that of the relation of human tuberculosis to that of bovines. The results of these investigations were published in 1903, and were directly opposed to those of Koch. The publication of subsequent reports has confirmed its conclusions. Professor Hamilton became a Fellow of the Royal Society last year. He was also a Fellow of the Royal Society of Edinburgh, and a Member of the Royal Medico-Chirurgical Society of Edinburgh, and of the Physiological, Pathological, and Neurological Societies.

A notable and striking tribute to his work was the issue in connexion with the university quatercentenary celebrations in 1906 of a volume entitled *Studies in Pathology*, consisting of contributions by his past students, designed

also to commemorate the fact that he had all but completed a quarter of a century's tenure of the Chair of Pathology. The volume was edited by Dr. William Bulloch, and among the contributors were Dr. Leslie Mackenzie, Dr. Arthur Keith, Dr. A. R. Cushny, Dr. George Dean (who succeeded Dr. Hamilton in the chair of Pathology), Dr. G. M. Duncan, Dr. Alexander Low, and Dr. J. J. R. Macleod.

Professor Hamilton was a man of culture and refinement. He loved art and music, and was a discerning critic of both. One of the features in the excellent pathological museum which he built up in Marischal College is the collection of models of pathological specimens, most of which were painted by himself. He was deeply interested in architecture, and his knowledge of its principles was wide and accurate. Many will recall his outspoken criticism of the scheme of decoration carried out in the restoration of King's College Chapel. Professor Hamilton frequently lectured in public on subjects connected with art, and the attractive and popular gifts which distinguished him in the classroom were equally present on the platform. His resignation of the Chair of Pathology was deeply regretted by his colleagues, and cordial recognition made of his great services to the university.

Professor Hamilton was essentially a generous-minded warm-hearted man, and his death, regretted by old students in all parts of the world, will be greatly mourned by all who enjoyed his friendship and knew him in the private relationship of life. He was twice married, and his second wife, a daughter of Mr. John Wilson, South Bantaskine, Falkirk, died in June last year. Professor Hamilton is survived by two sons and a daughter. Both sons are in the medical profession—one in Liverpool and the other in the navy. The daughter is the wife of Dr. Thomas Lumsden, London. Mr. Geo. G. Hamilton, until recently Surgeon to the Royal

Infirmary, Liverpool, was his brother.

The funeral took place on February 22nd from the university. The service was held in Marischal College, and the coffin, which was carried by four Shore Porters (a kind of guild), was preceded by the university senators, professors, and other members of the university in cap and gown, and followed by the chief mourners. The whole two miles from the college to the cemetery was lined by people, who doffed their caps as the coffin passed.

We are indebted to Professor ALEXANDER OGSTON for the following personal appreciation:

It will be many years ere Professor Hamilton be forgotten in his university or in Scotland.

He came to Aberdeen in 1882 to raise the subject of pathology from the degraded condition into which it had fallen and restore it to its proper place in the medical school of Aberdeen. A strong man, a determined man, a brilliant man was needed, and Hamilton was all this.

Framed by Nature in a fighter's mould, with the head, the face, the physique of a combatant, we were not long in learning Hamilton's energy and force of character. From the first day of his professorship it was felt that his conduct of the chair was to be on a level above what we had seen here, or indeed in almost any other school in the world. Some of us knew the teaching of Rokitsansky and the great Virchow, and our ideas were high-pitched; but Hamilton surpassed them. He started as a teacher far above the level of Virchow, and he continued his work to the end on a level that we could find nowhere else. A great defect was filled, and his colleagues as well as his students felt the benefit and responded to the stimulus.

Hamilton was not always right in his teaching. Who is? But at least his students left him knowing their pathology thoroughly, and it was better to know Hamilton's views well than to have drifted through the teaching of a feeble man. When he taught a thing he did it so that all his students understood and knew, and did not forget. A quarter of a century of strong men went out into the world well armed for their life-work and equipped with a goodly share of the energy and decision of their teacher.

But there was a softer side to our colleague. He was not all warlike. Once he knew a man to be straight and honourable, Hamilton showed him an unexpected aspect—that of the true, warm-hearted friend, who could be as kind and generous as brave and strong men are, and who never turned to the right or to the left in his straightforward friendship. In a school of medicine the tone of the teacher has vast power. If his nature be a low one it infects and destroys. Ideals are low, and the morale of the profession receives a blow that long echoes in its ranks. But Hamilton's influence raised all who came in contact with him. We loved him; his students loved after they had ceased to dread him, and I am sure no student ever went through our medical school without being a better man for having known Hamilton.

Of his scientific work I say nothing—it speaks its own tale; and this is a personal appreciation, solely. But it was worthy of him, as it was bound to be, for all his great heart was thrown into it. His department, the museum he created, influences us still, and will long do so. When the end comes for any of us, it is well, though it be given to few, to leave such a life-record behind as did Professor Hamilton.

The Right Hon. ROBERT FARQUHARSON, M.D., writes: I am glad of the opportunity of placing a wreath of cordial and heartfelt appreciation on the too early grave of my old, valued, and respected friend, the late Professor Hamilton. His death was not unexpected, nor, under the circumstances, to be regretted, for he suffered from an incurable and painful disease, made all the more sad by his own intimate knowledge of the lingering steps leading to the inevitable end. His was emphatically a life too short for friendship, not for fame, and his memory will always linger in the grateful affection of his numerous and attached pupils now scattered over the world, who will, I hope, erect some permanent memorial of their great master. Only a few years ago a distinguished foreigner, who visited Aberdeen, said, "If you want to learn pathology properly you must come to Aberdeen," and he was right, for he found there not only a perfect and complete laboratory installation, but the infectious enthusiasm, the wise dogmatism, and the breezy combativeness, which, whilst shattering old and worn-out beliefs, re-examined those which seemed to be finally established, and built up firmly on the ruins of what he destroyed. His interests were widely varied; he sang admirably, had more than a competent knowledge of art, and I cannot doubt that our mutual friend, David Murray, remembers a week-end at Finzean spent in a series of pitched battles between him and his formidable antagonist. Many of us will miss him long and deeply, and his premature removal will leave a distinct gap in the special branch of science to which he devoted all the energies of a vigorous and suggestive mind, and his excessive and continuous devotion to which undoubtedly impaired his strong physique. His *Textbook of Pathology* still holds the field, but what most especially interested me in my capacity of landed proprietor were the epoch-making researches he was carrying on into the varied dis-

eases of animal and plant life. These were beginning to bear good and useful fruit, and I deeply mourn the lost opportunity of suggesting some fresh lines of investigation in the interest of agriculture.

We quote, by the kindness of the editor, the following paragraphs from an obituary notice written by Professor Hamilton's successor, Professor Dean, which appears in the issue of the *Edinburgh Medical Journal* for March:

Professor Hamilton was undoubtedly one of the leading teachers of pathology of his period in Great Britain. He spared no pains in making his lectures models of scientific exposition, and constantly kept before his pupils the value of experimental methods. His manner of lecturing was vigorous, incisive, and effective, with the result that he left on the students a vivid impression of the subject-matter with which he had been dealing. His whole system was a practical illustration of the value of first-hand knowledge obtained by observation on the part of the learner.

His teaching of pathological anatomy and histology was particularly effective. He would have the students always to be seen, and even the weakest men in every class were forced to carry away a certain amount of knowledge which they had acquired by their own observation under his compelling guidance. He thus trained those under him to become observers, and enforced on them the necessity of accurate method. He had no toleration for anything slipshod, and many have greatly benefited by his influence in this direction.

We also quote the following paragraphs from the same journal, written by one of Professor Hamilton's pupils during the time when he taught pathology in Edinburgh:

Amongst the old Edinburgh pupils of Professor Hamilton there can be but one feeling at his comparatively early death—that of the profoundest sorrow. Although it is more than a quarter of a century since he left Edinburgh, the impression made by his teaching is still fresh in their mind. They remember how he returned from Vienna full of enthusiasm for his subject, and with a thorough acquaintanceship with the then modern methods of pathological investigation, and how he triumphed over the difficulties in the shape of the miserably inadequate accommodation and equipment of the laboratory allotted to him, and made the first courses of practical pathological histology taught in Great Britain a conspicuous success. In these days practical pathology was a voluntary class, not required for graduation, but the influence of Hamilton's teaching was such that he attracted not only university students, but men from the extra-mural schools in Edinburgh and from other universities in Scotland. He had a marvellous faculty of compelling one, even in spite of oneself, to take an enthusiastic interest in his subject. It was simply impossible not to be attentive to and not to learn from Hamilton. His enthusiasm and the influence of his personality dominated every member of his class. While we recognized that he might not be always right in his views, we were constrained to be directly interested in his subject in such a way as to make it a working part of our mental equipment. Every one of us is grateful for his inculcation of the method of personal observation and for the mental discipline it gave us—much to be desired in these days of "spoon-feeding."

In Aberdeen he has trained up a school of pathologists whose works have already done honour to their university. In Edinburgh he had begun to do the same, and more than one occupant of a pathology chair owes his position to the direction given to his studies by Hamilton. All over the world there are men who have carried into their daily work the habits of close observation and of clear thinking, for which they can never cease to be grateful to their old master.

PETER HORROCKS, M.D., F.R.C.P. LOND.,

SENIOR OBSTETRIC PHYSICIAN TO GUY'S HOSPITAL.

We regret to have to announce the death, at the age of 56, of Dr. Peter Horrocks, Obstetric Physician to Guy's Hospital. In the summer of 1907 he had some vesical hæmorrhage, and about Christmas time some growth was removed by operation; improvement was obtained, but there was a recurrence of the symptoms some months later, and their increase was such that a more extensive operation was attempted on Wednesday, February 24th, 1909, but unfortunately only partial relief could be obtained, and he succumbed on February 28th.

Peter Horrocks was the seventh son of the late Mr. George Horrocks, of Farnworth, near Bolton. He matriculated at the London University, and having passed the preliminary scientific examination from Owens College, Manchester, he entered Guy's Hospital in October, 1875. There he promptly made his mark, taking a prize for general proficiency at the end of his first year, and passing the First M.B. of the London University at the end of his second year, with Honours in Physiology. In his third year he obtained the second prize, and a year later he secured the Treasurer's Gold Medal in Medicine, and

followed this quickly by taking the degree of M.B. with the Gold Medal in Medicine, marks worthy of the Scholarship, and Honours in Obstetric Medicine. In the following year he obtained his M.D. degree. This successful career marked him out for a place on the teaching staff, and he became a Demonstrator of Anatomy in due course. His intention at that time was to apply for the post of Assistant Physician at Guy's Hospital when a vacancy should occur; and while waiting he undertook the charge of the Electrical Department of Guy's Hospital, and was appointed Assistant Physician at the National Hospital for the Paralyzed and Epileptic. He devoted himself there to the study of nervous diseases, and he entered upon a study of what was then a relatively new subject, and wrote for the *Guy's Hospital Reports* an article, Reflex Action in Diagnosis. He dealt fully with the matter, and supported his conclusions by original experiment. But this was not, after all, to be his life's work, for the impending resignation of Dr. Braxton Hicks led him to turn his attention to obstetrics, and he applied for and was appointed Assistant Obstetric Physician to Guy's Hospital, while Dr. Galabin was appointed to succeed Dr. Hicks as physician.

He threw himself into the duties of this post with the energy he had shown in all his other work, and soon attracted appreciative classes to his out-patient demonstrations and patients to his practice. Dr. Horrocks came into the field of obstetrics at the happy moment when the claims of the hospital obstetric physician to operate in any case of disease peculiar to women had been practically established, and he proved himself to be a bold and successful, at the same time careful, operator. He was a popular lecturer, for he had the faculty at all times, whether in consultation or *ex cathedra*, of putting what he had to say in a clear and emphatic manner, so that it was impossible to misunderstand either his meaning or his intentions: and the value of his opinion and of his manipulative and operative skill were such that his help was extensively sought for, and he comparatively early had a large practice, which he maintained until the end.

He was elected a Fellow of the Royal College of Physicians in 1889, was Honorary Secretary of the Obstetrical Society in 1890 to 1893, and President in 1901 and 1902, in which capacity he delivered two presidential addresses. He was not a great writer, but he made a few communications to the *Obstetrical Society's Transactions*, and delivered the Hunterian Oration before the Hunterian Society in 1898.

Horrocks was as full of physical energy as he was of mental activity. In his early days he was fond of boating on the river, but for some years he was devoted to alpine climbing, and in 1894 he had an experience in Switzerland which would have damped the ardour of most men effectively. While climbing a narrow ledge on the Zinal Rothhorn he was dragged from his steps by the slipping of a stone from under the feet of one of his guides. All three were hurled down the cliff. Horrocks was happily stopped by the rope catching on a projecting piece of rock; but one of the guides, from the breaking of the rope, was dashed down and killed on the glacier below. Horrocks and the other guide were luckily rescued by another party then on the mountain.

This hairbreadth escape did not prevent Horrocks enjoying the Alps on subsequent occasions: he did many climbs after this, and was among the mountains so recently as last year. He was a staunch friend; cheerful, genial, full of anecdote and reminiscence, with a keen enjoyment of an active, strenuous existence. He was unmarried, and his last year had been saddened, not only by his own threatening illness, but by the loss of more than one member of his family.

ACCORDING to statistics recently issued by the Austrian Minister of Education, the total number of students in the universities of Austria on December 31st, 1908, was 25,883: of these 4,324 were students of medicine. Vienna had 1,972, including 73 women; Innsbruck, 197; Graz, 361, including 4 women; the German University of Prague, 344, of whom 9 were women; the Czech University of Prague, 631, of whom 19 were women; Lemberg, 304, including 37 women; Cracow, 515, of whom 51 were women.

The Services.

ROYAL ARMY MEDICAL CORPS (TERRITORIAL).

EXAMINATIONS FOR PROMOTION.

WE have received the following communication:

I am a Lieutenant-Colonel in the R.A.M.C.(T.), and a few days ago I received a letter from the G.O.C. of my Division asking me when I was going to qualify for a Lieutenant-Colonel. I did not know until then I had to pass another examination, already having passed for Captain and Major. Upon looking up the subjects for examination, I found the following:

1. Army medical organization in peace and war.
2. Sanitation of towns, transports, and all places likely to be occupied by troops in peace and war, epidemiology and management of epidemics.
3. (a) The medical history of the more important campaigns, and the lessons to be learnt therefrom.
(b) A knowledge of the Army Medical Services of the more important Powers.
- (c) The laws and customs of war, so far as they relate to the sick and wounded.
4. Military law, as applicable to other officers of the Territorial Army.

In drawing up the above programme of examinations, it could not have entered into the heads of the Army Council that the men who have to pass in these subjects are senior men in large practices, with very little time for outside reading, and with the best will in the world few can afford to give the amount of time necessary to fit them up for examination. Take subject 3 (a), there alone is an enormous amount of reading, the medical history of the South African war is 400 pages, etc., what good can 3 (a) and 3 (b) do when a Territorial officer has passed in them? 1, 2 and 3 (c) are all right, and if they had kept to them no one could object. Numbers 1 and 4 are subjects already passed for a Major's examination: why put them in again?

I am writing this not to grumble, but to get the opinion of some more of the senior men of the R.A.M.C.(T.). No one could object to having all the officers as efficient as possible, but the authorities should consider that we have our livelihood to get outside the R.A.M.C.(T.) and are not allowed study time off. The only outcome I can see is that they will lose good men to the service who are willing to serve but have not the time to give for such stringent examinations.

THE ARMY ESTIMATES.

MR. HALDANE'S MEMORANDUM.

THE Secretary of State for War has issued the usual memorandum on the army estimates. The total for 1909-10 is estimated at £27,435,000, a decrease of £24,000 as compared with 1908-9, a result dependent upon considerable variations in both directions, the chief items of increased expenditure being the vote for the growth of the Territorial Force, which amounts to £355,000.

Recruiting for the regular army has been remarkably brisk, and at the present time fully-trained men are available to mobilize and maintain in the field for six months the cavalry division, complete with its due proportion of other arms, and the infantry of six divisions. The other fighting units of the six divisions can also be completed on mobilization, but there are still deficiencies in two divisions in the Army Service Corps and the partially-trained men required for medical units, and in the artillerymen required for ammunition columns and to supply the waste of war. The machinery for completing all these deficiencies has been organized and is at work.

Loss by Disease.

Under this head Mr. Haldane says:

"The time has come when we may gauge the results on the health of the army of the reforms in the Royal Army Medical Corps which were instituted in 1902. We are sufficiently removed from the disturbing influences of the South African war upon the normal statistics to be able to contrast the wastage from deaths and invaliding at the present day with that of the period preceding the war."

He gives a comparison of the hospital admission rates,

death-rates, rates of invaliding and constantly sick, rates of the first and last years of the decennial period 1888-1907 in India, in the United Kingdom, and in the Colonies, but we replace these by detailed statistics for each year from 1888 to 1907:

UNITED KINGDOM.

Average Strength for Period (1888-1907), 104,929.

Ratio per 1,000 of strength.

Years.	Admitted into Hospital.	Died.	Discharged as Invalids.	Constantly Non-effective from Sickness.
1888	740.9	5.52	15.91	44.45
1889	730.4	4.57	15.89	41.48
1890	810.6	5.53	16.72	44.29
1891	772.2	4.94	14.51	41.66
1892	761.3	4.38	14.38	42.75
1893	751.6	5.13	15.70	44.10
1894	655.9	3.70	17.06	40.91
1895	702.8	4.32	16.57	41.76
1896	645.1	3.58	21.20	33.52
1897	640.6	3.42	19.87	37.95
1898	649.6	3.59	17.99	37.84
1899	670.6	4.30	18.12	36.93
1900	655.1	6.62	32.85	34.24
1901	747.1	4.71	42.26	43.60
1902	711.2	4.18	36.67	41.65
1903	585.0	3.41	21.83	35.23
1904	505.7	2.96	21.59	29.26
1905	448.8	2.73	18.22	26.39
1906	446.7	2.92	14.40	24.86
1907	438.0	3.14	14.22	24.64

INDIA.

Average Strength for Period (1888-1907), 67,406.

Ratio per 1,000 of strength.

Years.	Admitted into Hospital.	Died.	Sent Home as Invalids.	Discharged as Invalids.	Constantly Non-effective from Sickness.
1888	1,385.7	15.20	22.85	12.43	72.34
1889	1,504.4	17.12	26.08	13.33	87.36
1890	1,517.1	14.45	25.42	16.99	86.96
1891	1,387.3	16.35	27.09	15.50	80.22
1892	1,514.7	17.59	24.41	12.40	83.88
1893	1,416.8	13.15	25.32	10.51	86.60
1894	1,506.9	16.81	25.37	15.17	91.71
1895	1,460.0	14.31	24.34	12.01	93.61
1896	1,386.7	15.29	27.89	12.48	95.85
1897	1,500.4	19.25	34.99	20.16	101.38
1898	1,454.0	20.31	39.45	19.94	90.75
1899	1,448.7	13.26	31.57	14.30	75.00
1900	1,143.2	15.36	33.46	11.18	71.71
1901	1,104.3	13.12	39.28	8.60	66.90
1902	1,078.4	15.36	37.23	13.55	66.00
1903	1,035.5	13.33	29.62	13.05	63.17
1904	897.0	11.28	35.59	17.20	57.14
1905	833.6	10.38	21.21	12.30	52.41
1906	871.0	10.81	28.37	9.39	51.47
1907	756.4	8.38	25.47	8.84	46.38

COLONIES.

Average Strength for Period (1888-1907), 90,744.

Ratio per 1,000 of strength.

Years.	Admitted into Hospital.	Died.	Sent Home as Invalids.	Discharged as Invalids.	Constantly Non-effective from Sickness.
1888	785.6	8.46	19.50	10.78	47.40
1889	762.3	6.94	23.42	11.85	48.04
1890	801.7	8.49	22.60	14.79	48.04
1891	778.1	7.33	20.86	13.65	48.67
1892	827.7	8.15	20.90	11.25	50.28
1893	923.4	8.15	21.57	11.58	57.03
1894	838.2	7.01	16.34	9.27	55.25
1895	894.2	7.73	17.00	10.29	57.72
1896	880.3	7.23	18.22	8.29	56.71
1897	904.2	7.99	21.34	10.45	57.11
1898	1,000.3	13.63	44.83	11.67	60.49
1899	846.8	7.91	29.20	12.68	50.66
1900	814.3	7.07	23.80	9.02	46.44
1901	801.0	9.77	47.10	12.99	48.35
1902	549.0	7.03	36.80	5.88	35.47
1903	740.0	8.47	33.04	19.45	51.24
1904	610.4	7.50	24.94	14.69	40.85
1905	565.1	6.21	27.57	10.72	36.26
1906	505.9	4.55	21.76	8.90	32.92
1907	502.3	5.16	19.83	9.01	32.77

These years were affected by the Soudan campaign.

In commenting on the statistics, Mr. Haldane says:

"It should be mentioned that the fall in the admission and constantly sick rates is not to be attributed wholly to diminished incidence of disease. It is partly due to an administrative improvement by which men with slight ailments are not removed to hospital, but are treated in barracks as out-patients. But the lowered death and invaliding rates show the true effects of efforts at disease prevention. The same results are shown, for specific diseases, in the curves published in the Army Medical Department Report for 1907-8.

"And this improvement is not only welcome as indicating increased well-being for the soldier; it also means reduction in the number of hospital beds necessary, less men maintained in peace to produce a given number fit for war, smaller annual drafts to be sent out by the home units; in fact, an all-round saving in the cost of the army."

The Territorial Force.

The Yeomanry and Volunteers on March 31st, 1908, numbered 9,174 officers and 241,085 men; the Territorial Force came into being on April 1st, 1908, and on December 31st, 1908, its strength was 8,623 officers and 199,059 men. Mr. Haldane states that since the work of administration has been handed to the county associations on April 1st, 1908, one of the largest questions engaging their attention has been

the provision of drill hall and other accommodation for the Force. This necessitated a large amount of new construction, and in many cases the adaptation or repair of what was already in existence. A number of new drill halls and head quarters have been approved, and in several cases riding schools for the use of the mounted branches have been sanctioned. Good progress is being made with this work, though it will take some time to complete.

The equipment of the force up to the standard required for training is being pushed forward, and it is intended that the necessary equipment shall be available for all units next training season.

There is every indication that the Territorial Force is making substantial and satisfactory headway in the country. Thanks chiefly to the efforts of the associations, it is receiving support from many who have not hitherto identified themselves with the military forces of the Crown. In particular, many large employers of labour, both public and private, are granting their employees the most generous facilities for attending camp. A general interest in the force has been awakened throughout the country; a considerable number of men whom the old volunteer organization does not appear to have reached are coming forward, recruiting is particularly brisk in consequence, and the class of men presenting themselves for attestation is exceptionally good.

Pay, etc.

The estimate for expenses of pay, etc., of the medical establishments and of medicines is £440,000; this is a net

decrease of £11,000, and as to this the estimates contain the following observations:

The return of medical officers and nurses from South Africa on reduction of the Garrison enables the numbers of re-employed retired officers and civil nurses to be reduced. There is also less provision for civil practitioners, owing to the increased number of officers of the R.A.M.C. available for duty.

ARMY MEDICAL CORPS (TERRITORIAL FORCE). ABERDEEN.

Head Quarters.—No definite decision has yet been reached as to where the permanent head quarters of the Royal Army Medical Corps and allied branches of the Territorial Force in the City of Aberdeen are to be, and it seems very doubtful whether the old West Poorhouse in Fonthill Road, which is at present being utilized as head quarters, will be purchased by the War Office as was expected and as is desired by the City Association. Since the R.A.M.C. has occupied these premises they have been found in every way suitable, being both commodious and central, and there is little doubt that those factors have counted very materially in the recruiting. Some few weeks ago the Chief Engineer for Scotland accompanied by the local officials of the City of Aberdeen Territorial Force Association, went over the premises, and also inspected the at present unused barracks in King Street. The old Poorhouse, although considered in every respect suitable for head quarters, was looked upon with disfavour on account of the cost involved in purchasing the building, and as there is still about twenty years of the lease of the King Street barracks to run, it has been suggested that these be permanent head quarters. This is viewed with much disapproval by the corps, not only because the place is in a bad state of repair, but also on account of its being so much out of the way for the great majority of the men. There can be no doubt that if the War Office eventually determines to make the barracks the head quarters of the R.A.M.C. this will have a very prejudicial effect on the strength and prosperity of the corps. Hopes are, however, still entertained that the representations of the association in regard to the purchase of the old Poorhouse may be favourably considered.

Recruiting.—Meanwhile the recruiting for the corps goes on very steadily and a good class of recruit is being obtained. For Nos. 1 and 2 Highland Division Field Ambulances and the General Hospital over 400 men have now been enrolled. The nursing staff of the General Hospital was complete some months ago—the first in the kingdom to attain this satisfactory position. The organization of the training school was completed many months ago, but as no funds are yet available for it little has been accomplished in the way of practical work. With suitable head quarters permanently agreed on there is no doubt that the corps would rapidly follow the Highland Division Artillery in completing its establishment.

Universities and Colleges.

UNIVERSITY OF LONDON.

FACULTY OF MEDICINE.

Proposed Formation of a Board of the Faculty.

THE Faculty of Medicine of the University of London, at its meeting this (Friday) afternoon, will have before it a memorandum by Professor Starling suggesting the formation of a Board of the Faculty, and draft recommendations and a draft resolution for the formation of such a board prepared by Professor Starling and Mr. Leonard Hill.

Professor Starling's Memorandum.

The main object of the reconstitution of the university in 1898 was to make the university a teaching body by giving the teachers a voice and an influence in the determination of the curricula and in the examinations. In the statutes of 1900 the method adopted to attain this object was the institution of boards of studies composed of teachers, whom the Senate were bound to consult on all subjects concerning the curricula and examinations. The recommendations of these bodies are considered by the Senate only after receiving a report on them from the Academic Council or External Council according as the recommendations affect internal or external students respectively.

To the Faculties the only statutory power accorded is the election of sixteen members of the Senate—members who also form part of the Academic Council. On the Academic Council there falls the task of co-ordinating the recommendations of the various boards within the purview of each Faculty, and of formulating definite recommendations to the Senate with regard to the Faculty as a whole. Since the Academic Council includes representatives from all Faculties, it has become customary for the affairs of each Faculty to be referred first to a subcommittee consisting of the representatives of the Faculty in question. The initiation of action in the internal affairs of the university so far as concerns medicine is therefore practically in the hands of the three representatives of the

Faculty. These three are not trained administrators. They are not cognizant with all aspects of questions which arise concerning the Faculty of Medicine. They only form a small minority in the Academic Council. Where there is general agreement between all the Boards of Studies they are able to advise the Academic Council accordingly. Where there is disagreement they have not the knowledge or power which would enable them to decide between the divergent views, nor, if they so decided, could they speak with the authority necessary to impress their views on the rest of the Academic Council or on the Senate. Moreover, their time and energies are so fully taken up with routine business, such as modifications in the curricula, recognition of teachers, course of study, etc., that no time or energy is left for the working out of schemes for the development of the University Faculty of Medicine, which have from time to time been put forward by the Faculty or the Boards. One of the weaknesses of the internal side of the University is the inadequacy of the Academic Council to perform duties which cannot possibly be carried out by any one body of men.

Is it possible to improve this condition of things? Any alteration in the mode of appointment of the Boards of Studies, or of the Academic Council, or in the reference to these bodies, would amount to an alteration of the schedule to the Act of 1898, which at present keeps the whole university in fetters. We cannot, therefore, expect any such alteration until the new Royal Commission has reported. It would, however, be possible to effect certain changes by consent (not by statute) which might bring about an improvement in the administration of the internal side of the university, and might be regarded as an experimental trial of a condition of things for which statutory authorization might be hoped for under a new Act.

We cannot expect the medical side of the university to make any substantial progress until its academic direction is determined by those who are mainly responsible for its welfare—namely, the members of the Faculty of Medicine. At the present time the Faculty itself is too large and unwieldy a body to undertake administrative functions. Any attempt to rule the medical side of the university by a direct vote of the Faculty would result in important questions being decided by small groups of men who had the energy or leisure to whip up the holders of some particular view. On the other hand, its three representatives on the Academic Council are too few in number and not sufficiently representative of the varied interests involved to be able to carry on the work which is laid upon them.

The solution of the difficulty is probably to be found by adopting the suggestion of the Cowper Commission, and by entrusting the affairs of the Faculty to a "Faculty Board," to be elected by the Faculty, sufficiently numerous to include representatives of the various branches of study involved in the medical discipline but not too large to act as a single advisory or executive body. It is to be hoped that such a body will in future be entrusted with actual executive functions in certain academic matters. At the present time all that the Faculty can do is to delegate its powers of advice to its representative board, and to request the Senate to regard its delegates as the Faculty itself and as the chief advisory body in medicine. The Faculty Board would thus in practice take the place of the subcommittee in medicine of the Academic Council, and would probably also render unnecessary the existence of the committee of the medical members of the Senate.

Method of Appointment.—At some future time, when the Faculties have more autonomy and are directed by their representative boards, the nomination of Boards of Studies, which might be practically committees of the several Faculties, would lie with the latter. At present the Boards of Studies are the most important academic bodies provided for by statute. The Faculty Board would therefore have to be, in the first place, representative of the various Boards of Studies in the Faculty, care being taken by the proper proportioning of the numbers of representatives from each board, and by the addition of members directly elected by the Faculty to ensure that the opinion of the Faculty Board should really represent the opinion of the Faculty as a whole. A board of twenty-four to thirty would be workable in size, and might have somewhat the following constitution:

One representative of each of the subjects, Chemistry, Physics, Biology, Pharmacology, Ophthalmology, Hygiene, Mental Diseases, Dentistry—8.

Two representatives of each of the subjects, Anatomy, Physiology, Pathology, Gynaecology—8.

Five representatives each of Medicine and Surgery—10.

This would give eight members of the board representing the Preliminary and Intermediate Medical Studies and eighteen representatives of the Advanced Studies. In a

body of this size it should be possible to secure representation on the board of every school of the university. The board would have to meet regularly at least once a month in order to get through the business, and it would therefore be essential to elect only such men as are able to devote this amount of time to the work of the Faculty.

The following series of resolutions are designed for the purpose of carrying these alterations into effect. It is important to remember that the Faculty, in carrying these or similar resolutions and making a bid for Home Rule in the Faculty, would be practically requesting the Academic Council to abrogate certain of its powers in favour of a board which is not recognized by the present statutes. The change, therefore, can only be carried out by consent of the Senate and its Councils, and if the recommendations of the Faculty are to have sufficient weight with the Senate to persuade this body of their advisability, it is essential that they should be carried by a large majority at a full meeting of the Faculty, and not, as usually happens, by a chance majority at a meeting which only just exceeds the necessary quorum. The question is vital for the future of the Medical School of London, and is much more important than the election of one or other individual as a representative on the Senate. It is hoped, therefore, that the members of the Faculty will make a special effort to attend the meeting at which these resolutions will be brought forward.

Draft Scheme Proposed by Professor Starling and Mr. Leonard Hill.

The scheme recommends that the Board of the Faculty of Medicine shall consist of:

- (i) The Dean of the Faculty of Medicine, who shall be *ex officio* Chairman of the Board.
- (ii) The Secretary of the Faculty of Medicine, who shall be *ex officio* Secretary of the Board.
- (iii) The Chairmen of the Boards of Studies in the following subjects:

Preliminary Medical Studies,
Intermediate Medical Studies,
Advanced Medical Studies,
Dentistry,
Hygiene and Public Health,
Physiology and Experimental Psychology,
Human Anatomy and Morphology.

- (iv) Representatives of the following boards appointed by the Faculty after report from the Board in question, namely:

Two representatives of the Board of Preliminary Studies,
Two representatives of the Board of Intermediate Medical Studies,
Four representatives of the Board of Advanced Medical Studies.

- (v) Four members to be elected from the Faculty by the Faculty.
- (vi) The three Representatives of the Faculty of Medicine on the Senate.
- (vii) The two members of the Senate appointed by Convocation on the election of the registered graduates in Medicine and in Surgery.
- (viii) All members of the Faculty of Medicine not included in the foregoing categories who are also members of the Senate.

The Board will thus consist of at least twenty-six members, and it is proposed to fix its quorum at ten.

It is recommended that the Board of the Faculty of Medicine be empowered to report to the Senate on any subject within the purview of the Faculty through the Academic Council, or through the Council for External Students, as the case may be, provided that, if any six members of the board, at any meeting of the board, request that a question shall be reserved for the consideration of the Faculty as a whole, no action shall be taken thereon until the Faculty has considered it.

Resolution.

The following is the text of the resolution which is to be proposed by Professor Starling, seconded by Mr. Leonard Hill:

That the Senate be requested to resolve that until further order no action on any of the following subjects be taken by the Senate until they shall have received a report thereon from the board of the Faculty of Medicine through the appropriate council or councils in accordance with the scheme set out below:

Subject.	Appropriate Council.
(a) Recognition of teachers and courses of instruction in medical subjects	Academic Council.
(b) Medical curriculum	Academic Council and External Council.
(c) Medical examinations, including appointment of Examiners	Ditto.
(d) Admission of schools in the Faculty of Medicine	Academic Council.
(e) Constitution of the Faculty of Medicine	Ditto.
(f) Organization of higher teaching and research in medicine	Ditto.

UNIVERSITY OF CAMBRIDGE.

The date of the Third M.B., Part II, in next Easter term, has been altered from Tuesday, June 15th, to Tuesday, June 8th, owing to the Darwin celebration.

R. C. Pannett, M.A., Gonville and Caius College, has been appointed Superintendent of the Zoology Museum.

Sir Victor Horsley will deliver the Lincace Lecture at St. John's College on May 6th, the subject of the lecture being the Motor Area of the Brain.

The following degree was conferred on February 25th:

M.B., B.C.—F. A. Julea, Trin.

UNIVERSITY OF ABERDEEN.

HONORARY GRADUATES.

At a meeting of the Senatus of Aberdeen University held on February 23rd it was agreed to confer the following honorary degrees at the April graduation:

The Degree of Doctor of Divinity—Rev. David S. Cairns, M.A. Edin., Professor of Domestic and Apologetics, United Free Church College, Aberdeen; Rev. James Riddoch Leslie, M.A. Aberd., Principal of the Episcopal Training College, Edinburgh; Rev. John Scott Lidgett, M.A. Lond., Warden of Bermondsey Settlement, London.

The Degree of Doctor of Laws—Allan Rannie Andrew, M.A. Aberd., Chief Inspector of Schools, Hamilton; Alexander Bruce, M.A. Aberd., M.D. Edin., Edinburgh; Donald Crawford, K.C., Sheriff of Aberdeen, Kincardine and Banff; Frederic Harrison, Philosophical Writer, London; James Pittendrigh Macgillivray, R.S.A., Sculptor, Edinburgh; Paul Sabatier, French Author.

Dr. Alexander Bruce had a brilliant career as a student at Aberdeen University. He was first Bursar in Arts in 1870, and graduated in 1874 with first-class honours in classics, and gained the Simpson Greek prize, the Seafield gold medal in Latin, and the Town Council gold medal as the best student of his year. He studied medicine in Edinburgh, and graduated in 1879 M.B. and C.M. with first-class honours, gaining the Grierson and Tyndal Bruce bursary and the Edlies and Leckie Macstair scholarship. Later he took his M.D. degree, gaining the gold medal for his thesis. For many years he was Lecturer in Pathology in the Edinburgh Medical School, and held the post of Pathologist in the Edinburgh Royal Infirmary and in the Royal Hospital for Children. He is now Lecturer on Practice of Medicine and Physician to the Royal Infirmary, Edinburgh.

UNIVERSITY OF BRUSSELS.

The following candidates were successful at the last examination for the degree of Doctor of Medicine:

Dr. B. J. Macaulay, Eastbourne; Dr. H. F. Briggs, Eastbourne; Dr. A. R. Rendle, Harrow; Dr. J. J. Bradley, Colonial Medical Officer, Seychelles.

TRINITY COLLEGE, DUBLIN.

FINAL EXAMINATION IN MEDICINE (PART II).

The following candidates passed this examination in Hilary Term:

J. H. Woodroffe, 'M. A. Diemont,' Hilgard Müller, A. K. Henry, A. C. Hallows, Beatrice M. Hamilton, C. H. Denham, R. H. Mathews, P. G. Leenane, J. W. Flood, J. E. Burgess.

'Passed on high marks.'

SOCIETY OF APOTHECARIES OF LONDON.

Gillson Scholarship in Pathology for 1909.—This scholarship has been awarded to Mr. P. N. Paton, M.A., M.B., (C.M. Camb.), M.R.C.S., L.R.C.P. Lond., of Cambridge University and St. Thomas's Hospital.

The following candidates passed in February in the subjects indicated:

SURGERY.—W. C. DeBath, Charing Cross.

MEDICINE.—N. B. Pensabedi (Sections I and II), University College Hospital; J. Bramley-Moore (Section D), University College Hospital; J. H. Clarke (Sections I and II), St. Mary's.

MIDWIFERY.—J. H. Clarke, St. Mary's; M. Graves, London; H. V. Humphry, Westminster.

Medico-Legal.

ACTION FOR ALLEGED NEGLIGENCE.

IN the Aberdeen Sheriff Court evidence was led last week in an action at the instance of the husband of a patient of Dr. J. A. Mearns and Dr. W. J. Bryce for £125 as damages from each of the defenders for alleged negligence in treating the pursuer during her confinement in February, 1908. She alleged that she was severely scalded by the use of hot water approaching boiling point. The allegations were denied.

In deciding the case, Sheriff Begg finds that the pursuer has failed to prove any fault or negligence on the part of the defenders, and he assuages them with expenses, finding, however, that no higher charges are to be allowed than would have been incurred if the defenders had lodged joint defences, and been represented by the same law agent. The sheriff remarked that this was a most painful case to decide on account of the mutual aspersions of the parties. On the one hand, he did not think there was any ground for accusing the pursuer of shamming or malingering. On the other hand, he could hardly understand how she suffered so severely from the application of water to her though he scalded the two doctors' hands, or how the

discoloration of the skin observed by Professor Stephenson developed into the raised scar tissue, upon which Dr. Wallace Milne required to operate. Various suggestions had been made to meet the difficulties, but none could be regarded as proved. In the absence of any proof of fault or negligence on the part of the defenders, he must regard the pursuer's scald as the result of accident, whether due to the abnormal sensitiveness of the skin of the pursuer, to the midwife allowing the sheet saturated with hot water to remain in contact with the skin, or to some unascertained circumstance. Even in hospitals, where patients had the advantage of the highest skill and the most scientific appliances, slight blisters had been known to result from the hot water treatment of hæmorrhage. He sympathized with the pursuer, but doubted whether she would have raised this action if she had known that in all probability the defenders saved her life by promptly applying the only available remedy while she was under chloroform. If desperate diseases called for desperate remedies, a doctor might be pardoned for taking the risk of the water being rather too hot for the patient's skin instead of allowing the patient to bleed to death. It was common ground between the parties that this particular part could stand much greater heat than the external skin. As regards their subsequent treatment of the case, the defenders seemed to him to have fully done their duty. Dr. Byres, having been called to assist, was quite entitled to leave the patient to the care of Dr. Mearns. As regards the latter gentleman, he could not hold that he was bound personally to dress the pursuer's sore, considering that the nurse was quite fit to do so.

It may be gathered from the foregoing account that this was a case of uterine hæmorrhage treated by the application of hot water: it shows how medical men may be worried by actions for damages, and, though they gain a verdict in their favour, are saddled with a bill for heavy costs.

WORKMEN'S COMPENSATION.

Alleged Psychical Paraplegia.

BEFORE the Hon. the Recorder of Dublin, John Delany, a labourer, claimed an award against Messrs. Richardson and Fletcher, manure manufacturers, for injuries sustained to his spine and back while engaged loading manure in barrows in the defendant's premises.

The Recorder had the assistance of Sir Charles Ball as medical assessor.

John Delany, who moved about the court with the aid of crutches, stated he had been for eight months in the employ of this firm, and up to the time of the accident in question he had never had an hour's sickness in his life. The circumstances of the accident were that a heap of manure, 7 ft. or 8 ft. high, fell upon him, and he was struck unconscious. He was treated in Sir Patrick Dun's Hospital, the Meath Hospital, and the South Union Hospital, but was still absolutely disabled.

Dr. McNamara, called for the applicant, stated that Delany was suffering from injury to the spine, and was not able to work.

Dr. Charles Preston Ball, called for the respondents, stated that the applicant was well able to work, but imagined that he could not.

Dr. Parsons, who had examined the applicant on two occasions, stated that the man was suffering from no organic disease, and had not sustained any serious injury to his spinal column, such as fracture or dislocation. In cross-examination, asked how he could account for the man's allegation that he could not walk, Dr. Parsons said he could not do so except to this extent: it had got into Delany's mind that his back was injured, and as a result of this fixed idea in his mind he could not move his legs. It being put to Dr. Parsons that the man had come unscathed out of Sir Patrick Dun's, Meath, and South Dublin hospitals, witness replied that it was very difficult to persuade a man he had the capacity to walk, particularly when an action in court was pending.

Sir Charles Ball, the medical assessor, then saw the applicant in his Lordship's chamber, and upon returning, communicated his views to the Recorder, who stated that Sir Charles agreed with Dr. Parsons. He did not think this man was malingering, but that he was in a nervous and hypochondriacal condition, and that he was not fit to work at present.

The Recorder said there was an important question involved as to how far an accident could be held to be accountable for the man's mental condition as distinguished from physical injuries. He suggested, however, that some agreement should be arrived at between the parties.

On the consent of both sides the Recorder made an interim order for the payment of an allowance to the applicant, and adjourned the case till next session to see how he would go on. The Recorder commented on the enormous advantage of the aid of an assessor in those particular cases.

FEES TO MEDICAL WITNESSES FOR GIVING EVIDENCE AT INQUESTS IN WORKHOUSES IN IRELAND.

DR. T. LAFFAN (Cashel) writes with reference to this matter to say that he has received fees for giving evidence at inquests or making *post-mortem* examinations on patients who have died in workhouses. He considers that the law on the point is well ascertained.

MEDICAL FEES AT INQUESTS.

H. G., F.R.C.S., inquires whether a medical man is not entitled to receive an extra guinea for attending an adjourned inquest.

* * The coroner is only empowered to pay one guinea for evidence and one guinea for *post-mortem* examination, including adjournments. This is the highest fee that he can allow by statute law. But occasionally, when a special analysis is required, extra remuneration is obtainable from the Home Office or the county council.

THE MEDICAL WITNESS AT AN INQUEST.

THA writes as follows: Is it usual or proper for a medical coroner, who is also engaged in private practice, to systematically employ his partner to make *post-mortem* examinations and give evidence in his court, to the exclusion of other practitioners?

* * We think the coroner should summon to give evidence at the inquest the medical man who last attended the deceased or was called in at the time of death, and this is the usual practice. The coroner who systematically employs his partner, to the exclusion of another practitioner, can hardly be said to be exercising the duties of his office with dignity and discretion.

SHARE OF A PRACTICE.

PARTNER asks what would be a reasonable sum to pay for the third share of a practice, established fourteen years, bringing in £1,500 per annum, and what would be a reasonable time to wait before being admitted to a further share?

* * From the data it would be impossible to form any reliable opinion as to the actual value of this practice. Speaking generally, such a share would probably be worth from a year and a half to two years' purchase. With regard to a further share, this should be settled at the time of the purchase, and by mutual agreement. It is impossible to say on the data what would be a reasonable time to wait.

CORONER AND MEDICAL PRACTITIONER.

H. C. S. writes us a long letter in which he complains that, although called by a police constable to view a dead man with the head on one side of the railway line and separated entirely from the rest of the body, he was not summoned by the coroner to give evidence at the inquest; and further he asks who is responsible to him for the payment of his fee when called by the police to see the body? It appears that our correspondent did attend the public inquiry and the coroner explained to him that it was optional on his part as to whether he called a medical man or not, but the jury had the power to do so if they wished for further medical evidence as to the cause of death. The jury in the present case did not require medical evidence and returned an open verdict, which our correspondent believes would have been one of suicide had he been requested to give evidence. He received no fee at the court, and after a passage of arms between the coroner and himself, he left much dissatisfied with the proceedings. We sympathize with H. C. S. in the matter, and we think that the inquest would have been more satisfactory if further evidence had been taken than that given by a constable only. The position of the deceased's hat and stick, and other things, observed by the medical man called, indicated that the act was contemplated; and he says that if he had given evidence probably a more correct verdict would have been obtained. But he was neither summoned to attend, or permitted to give evidence at the court. For services rendered at the time he was called by the constable to see the deceased a claim should be made to the Chief of the County Constabulary, or he might be remunerated by the railway company or by the relatives of the deceased. A coroner has no power to issue payment to a medical man except for giving sworn evidence at an inquest or for making a *post-mortem* examination.

BOOK DEBTS.

S. R. P., who has bought a practice without buying the book debts, wishes to know if he must hand over to his predecessor money paid by patients for his work done since he has been by himself, because he finds in the ledger that they owe his predecessor an account. Should confinement fees be handed over also?

* * The purchaser of a practice can, of course, refuse to collect his predecessor's professional accounts; and in that case the vendor would have to take steps to realize them at once, if necessary by suing. As this usually would do damage to a practice, it is customary for the purchaser to consent to collect them in the ordinary way by sending in accounts periodically with any fresh items added thereto. Under such circumstances it is only just that when part payment is made the amount received should be used to cancel the earlier part of the account rather than the later. With regard to confinement fees it is another matter; they are special fees paid at the time for work done, and would belong to the purchaser.

RECEIPT STAMP.

WITH reference to an answer given in the JOURNAL of February 13th, 1909, p. 443, "R. R. R." writes: Your reply re receipt stamp is wrong. Both the name (or initials) and the date must be written across the stamp. Also the payment of an account without the stamp being so written over can be obtained again. You might note this in the BRITISH MEDICAL JOURNAL.

* * Our correspondent is really a little too positive. Section 8 of the Stamp Act, 1891, indicates the method referred to as a proper and sufficient method of cancelling a receipt stamp, but it is not the only method authorized. For his benefit we quote Subsection 1 in full, the italics being our own:

"An instrument, the duty upon which is required or permitted by law to be denoted by an adhesive stamp, is not to be deemed duly stamped with an adhesive stamp, unless the person required by law to cancel the adhesive stamp cancels the same by writing on or across the stamp his name or initials, or the name or initials of his firm, together with the true date of his so writing, or otherwise effectively cancels the stamp and renders the same incapable of being used for any other instrument, or for any postal purpose, or unless it is otherwise proved that the stamp appearing on the instrument was affixed thereto at the proper time."

Our correspondent's statement that if a person fail to stamp a receipt or to initial the stamp he can recover the money which has already been paid to him is also incorrect, for the reason given in our previous answer. The question is entirely one of evidence, and a document not duly stamped would not be admissible as evidence of payment. Other evidence might, however, be admitted, and payment proved without the production of the receipt being necessary.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

RELATIONS WITH AN UNREGISTERED DENTIST.

X. writes that opposite his house lives an unregistered dentist, who recently sent him a patient whose jaw had been dislocated. He reduced the dislocation and claimed his fee, but the patient demurred and said that the dentist said X. would not charge anything. X. therefore let him off the fee. He wishes to know whether he was covering an unqualified practitioner.

* * We do not see on what ground X. excused the patient a fee if he was able to pay one. Whether the dentist was registered or not would make no difference in X.'s obligation to render aid to the patient or his right to be paid for it. By not charging a fee he has laid himself open to the suspicion of occupying some special relation to the dentist, and we advise him to let the dentist know that he must not look to him in future for any assistance in his practice.

RELATIONS WITH UNQUALIFIED DENTISTS.

J. P. R. writes: I have been asked by an unqualified man practising dentistry to report upon a former patient of his upon whom he has operated who is now suing him for damages. He asks whether he would be justified in seeing this patient, and giving evidence in court on behalf of the unregistered dentist?

* * While the position of an expert witness giving evidence on behalf of an unregistered practitioner is not a desirable one, it does not seem to involve a violation of the resolution passed by the General Medical Council on December 1st, 1898.

SCHOOL DOCTORS AND THE HEALTH OF SCHOOL TEACHERS

HON. SEC. F. DIVISION.—(1) The duties of a school medical officer are prescribed by individual education authorities, but we do not know of any authority which has included in the duties of the office the examination of members of the teaching staff. (2) A school medical officer, whether whole-time or part-time, unless requested to do so by the teacher himself, should not examine a teacher without communicating with that teacher's doctor. An obvious exception would be in the case of suspected infectious disease, but even then after making a diagnosis the teacher's doctor should be written to by the school medical officer.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL

THE offices of the British Medical Association and of the BRITISH MEDICAL JOURNAL are at 429, Strand, London.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Office, 429, Strand, London, W.C.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Athology*, London. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate*, London.

TELEPHONE (National):—

2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.

2630, Gerrard, BRITISH MEDICAL ASSOCIATION.

2634, Gerrard, MEDICAL SECRETARY.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

We would request correspondents who desire to ask questions in this column not to make use of such signatures as "A Member," "A Member B.M.A.," "Enquirer," and so on. By attention to this request much confusion would be avoided. Correspondents are asked to write upon one side of the paper only.

F. M. would be much obliged for any information regarding the climate of San Luis Potosi, Mexico.

COST OF PETROL FOR MEDICAL MOTORING.

BOLTONIAN writes: The cost of petrol generally is assumed to be about 4d. per mile, or say, about 20 miles to the gallon, 1s. I should like the opinion of medical men if their running does not cost them more, as though not covering more than between 10 to 20 miles, taking three to four or more hours, the continual starting and stopping may make a difference.

HOSPITAL FLOORS.

B. G. M. writes from India: The new hospital here has been floored with marble slabs each about 18 in. square. Unfortunately the work has been badly done, and the joints between the slabs are open in many cases. The opening tends to the whole thickness of the slabs. The joints are wide enough to take the thin blade of a penknife. Would any of your readers kindly give me advice as to what should be done to fill up these openings in a way suitable for the requirements of a hospital floor? The best I can think of is plaster of Paris; but it is porous.

ANSWERS.

NEW ZEALANDER.—A New Zealand student, who has attended the University courses in Biology, Physics, and Chemistry (Inorganic and Organic), and has passed the examination for the degree of M.B. of the University in those subjects, is exempted from the equivalent examination for the diplomas of L.R.C.P. and M.R.C.S. Such a student, however, is not exempted from the Second Examination in Anatomy and Physiology for the diplomas of L.R.C.P. and M.R.C.S., unless he has passed the Final Examination for the degree of M.B. and has obtained that degree.

"BANDI'S LYMPH."

X. Y. Z.—Dr. Bandi, an Italian bacteriologist, has taken an active part in the vaccine campaign against various diseases, but, as far as we have been able to ascertain, he has not introduced any serum. His name is, however, associated with a plague vaccine, which, in conjunction with Dr. Terni, he described in the *Deut. med. Woch.*, January 19th, 1909, p. 465. This vaccine differs from Haffkine's method by precautions being taken to increase the virulence of the bacilli, and by taking the exudation from the peritoneal cavity of infected guinea-pigs and rabbits just before or just after death, and incubating this fluid for some time before sterilizing it by the fractional method. Priority was claimed by Dr. Bandi for the plague idea, when Hueppe and another worker dealt with this subject in 1907, and did not mention his name. He has also done work in connexion with diphtheria.

A CASE FOR DIAGNOSIS.

DR. H. J. THORP (Ipswich) writes: In reply to "B.S." in the *Journal* of February 27th, I would suggest the patient taking a minute dose, a grain, of calomel three times a day. The patient must submit to a strict régime of diet and exercise.

TREATMENT OF BRONCHIAL ASTHMA.

DR. F. P. BARTLETT (Ottawa St. Mary) writes: "A Medical Man" should try for his bronchial asthma Parke Davis 2-grain capsules of desiccated suprarenal gland. One taken three times a day and continued for some months.

LETTERS, NOTES, ETC.

THERMOMETER CASE.

MR. G. H. ZEAL (82, Turnmill Street, E.C.) has sent us a patent thermometer case with a clip to attach to the pocket, like the clip commonly used for carrying certain forms of fountain pen. The use of such a case may prevent some accidents.

THE SERUM DIAGNOSIS OF SYPHILIS.

DR. HARRY CAMPBELL (London) writes: It has been pointed out to me that in my letter published in the *BRITISH MEDICAL JOURNAL* of February 27th, p. 567, the phrase "the corpuscles are allowed to sink" is ambiguous. I ought to have said that "the blood is allowed to clot," and the supernatant serum drawn off.

TROPACOCAINE AS A SUBSTITUTE FOR COCAINE.

DR. GORDON SHARP (Leeds) writes: Some time ago the Pharmacopoeia Committee suggested the need for a substance having like properties to, but possessing less toxicity than, cocaine. It may be found that tropacocaine will answer the requirements, for present experience points to its being much less dangerous in use. It has one great advantage, in that it is not a proprietary preparation for it is found in coca leaves. Chemically it is a derivative of pseudopine and when hydrolyzed by boiling with a mineral acid it yields pseudotropine and benzoic acid. The commonest salt is the hydrochloride, and solutions can be boiled without undergoing decomposition. Cocaine, it may be remembered, is a derivative of eugonine, and when treated with baryta water it splits up into eugonine and benzoic acid. It has the disadvantage of being decomposed when boiled in plain watery solution. Three drops of a per cent. solution of the hydrochloride of tropacocaine instilled into the conjunctival sac produce anaesthesia in the same time as a like preparation of cocaine, enabling foreign bodies to be removed without pain, and a great advantage is that the pupil is not dilated, so that the patient is not troubled by double vision. Like cocaine, it appears to contract dilated blood vessels. I have seen a grain of the hydrochloride injected into the great toe of a girl of 15 with success, and without any disagreeable after-effects. Probably in spinal anaesthesia it might be used with safety. For many reasons it is worthy of more extended trial than has been given it in the British Isles. Merck's price for the hydrochloride is half a crown a gram (15.432 grains), but if it came into common use the price would no doubt be much less.

CREMATION.

M.D. F.F.P. and S.G. SLIGO, writes: Adverting to your article on cremation, nobody can deny that our present burial methods are the most unhealthy and revolting ever known to any people. You will remember that in a case of exhumation by Sir Thomas Stevenson lately, he found that two years after interment putrefaction was still active and intolerable. You have rightly pointed out that the opposition of the Catholic Church to the practice of cremation is an important factor which ought to be modified, if possible. As bearing on the subject it may be well to record the following excerpt from number 1, at a recent issue, of the *Catholic Times* of the current issue: "In conclusion, it must be remembered that there is nothing directly opposed to any dogma of the Church in the practice of cremation, and that, if ever the leaders of this sinister movement so far control the governments of the world as to make this custom universal, it would not be a lapse in the faith confided to her were she obliged to conform." This statement is the more important as being that of a writer in the *Catholic Encyclopedia*. It is a matter of grave moment that the Church was approached in the appropriate fashion. I would suggest that each Division of the British Medical Association should approach the bishop of the diocese with a statement of the great dangers to health caused in crowded communities by the present burial system—together with their views as to the sanitary value of cremation. It might also be pointed out that the ashes of the cremated could be preserved in the churches.

CAUSES OR CONSEQUENCES.

DR. ROBERT LEE (Pwllheli) writes: A few months ago I was consulted in a case that was diagnosed as "tuberculous meningitis." The infant was between 5 and 6 months old. The prognosis of the practitioner, a man of some experience and knowledge, was very unfavourable, and the family distress was great, as it was the first child. The usual symptoms were present—a condition of nervous prostration, semi-coma, the skin pallid, the eyes turned up and the left markedly inverted, the hands and legs slightly tremulous. I advised the old-fashioned treatment of a hot bath, large doses of calomel and small doses of Dover's powder, and cold applica-

tions to the head. My friend the practitioner smiled good temperedly at what seemed rather absurd treatment and the fully holding out any hope in such a case. Experience had taught me a good deal, and how very theoretical this tuberculous idea is in actual clinical work. Gradually the infant improved. In a week's time the brain inflammation subsided and things looked very different. In three weeks it was out of all danger and now is in perfect health. These forms of inflammation, which I see that Dr. Fisher and Dr. Card do not feel disposed to admit are tuberculous, are frequent in infants and children. The skin, the glands, the mucous membranes, the eyes, the ears, the joints, in fact all the tissues of the body in children, are liable to them, and they seem not to be caused by, or to be the consequence of, tuberculous infection. They do assume often a form of low and chronic character that led to such terms as the "King's evil," and scrofula. They look as if they are due to the constitutional conditions of the children, and are the consequences of any causes which lower their vitality and power of resisting the numerous agents that will attack the feeble and unhealthy.

A SANATORIUM CHART.

MESSRS. BAILE, SONS, AND DANIELSSON have published a chart for use in sanatoriums for consumptives which has the advantage of showing on a single sheet the records of temperature, pulse, respiration, weight, results of examination of sputum and blood, and the amount of rest and exercise for a period of three months. Though the temperature chart has, of necessity, to be closely ruled in order to get the thirteen weeks into a reasonable compass, it is clear and distinct. There is adequate space for all the other particulars of the case, including a weekly summary of progress. This sanatorium chart should prove of value.

THE COLD BATH TREATMENT OF TYPHOID FEVER.

DR. JOHN HADDON (Hawick) writes: Dr. A. J. Manasseh, in the *JOURNAL* of February 27th, p. 563, tells us that he has not tried the cold bath as a treatment of typhoid fever, but that cold sponging is efficacious. I tried the cold bath when it was first recommended by the Germans, troublesome as it was, and found that it did more harm than good; but, as if by accident, I discovered that the sudden shock of cold water thrown upon the patient had an excellent effect. On looking into the literature on the subject, I found that Dr. Currie, an Edinburgh graduate, who practised in Liverpool in the beginning of 1800, advocated cold effusion in the treatment of scarlet fever, and I found it was successful, but has found no treatment and well deserving to be resuscitated in the treatment of fevers generally. The shock to the nervous system which the cold water gives seems to stimulate some centre which is at fault when fever exists. It certainly does not act by cooling the body, as the cold bath was recommended to do, and as, I suppose, sponging is supposed to do.

MEDICAL FOOTBALL.

FOOTBALL has been suspended again almost entirely during the last week owing to frost and snow, and the match between Middlesex and St. Thomas's Hospital in the Cup Tie has been postponed. The only game of importance has been that of the London Hospital v. Harlequins, played in a blinding snow storm at Hale End on February 27th, and resulting in a win for the Hospital by a goal and try to nothing. Some of the credit in the victory to the London was lost owing to the fact that the absence of four of the regular players for the Harlequins necessitated a rearrangement of the back division. The Hospital, however, thoroughly deserved its victory, playing in fine form and passing and running very cleverly. The chief credit was due to Heale and Lindsay, who again and again saved almost certain tries by the spirited defence with which they prevented the attacks of the Harlequin forwards. Starting with the wind in their favour, the Hospital kept their opponents almost continuously on the defensive, and for minutes at a time there was no play. The Harlequins' line almost on the Harlequin's lines, but by half-time there had been no scoring. Within eight minutes after play was resumed, however, a bout of clever passing resulted in Palmer getting over the line by the corner. Then the Harlequins began to press, and the London had hard work defending until a smart kick by Lindsay gave Lloyd the looked-for opportunity and enabled him to touch down. The try was converted. The outstanding feature of the closing minutes was the series of brilliant but abortive runs by Lambert for the Harlequins.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under	—	—	0 4
Each additional line	—	—	0 0 6
A whole column	—	—	2 13 4
A page	—	—	8 0 0

An average line contains six words.

All remittances by Post Office Order must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

A Clinical Lecture

ON A

CASE OF HERNIA STRANGULATED IN THE FORAMEN OF WINSLOW;

AND THE

TREATMENT OF GREATLY-DISTENDED SMALL INTESTINE.

DELIVERED AT THE BRISTOL GENERAL HOSPITAL.

By CHARLES A. MORTON, F.R.C.S.,

PROFESSOR OF SURGERY IN UNIVERSITY COLLEGE, BRISTOL; SENIOR
SURGEON TO THE GENERAL HOSPITAL AND CHILDREN'S HOSPITAL.

GENTLEMEN,—The form of internal hernia, an instance of which I am about to describe—hernia into the foramen of Winslow—is a very rare form. There are only about a dozen cases on record (one was reported by Mr. Carwardine in the Infirmary last year), and there is only one successful case of operation for strangulation in this hernia. My own case was unfortunately not successful, but all the symptoms of strangulation were relieved by the release of the strangulated bowel from the foramen, and the patient seemed almost certain to recover, when, seven days after the operation, he died a few hours after developing serious symptoms, and we found *post mortem* some pelvic peritonitis, due to leakage at the attachment of the opened bowel to the parietal peritoneum, into the pelvic cavity. This certainly did not seem sufficient to cause his death, for he was a strong, middle-aged man, but nothing else was found *post mortem* that would account for it.

Mr. W. was seen in consultation with Dr. Burroughs at 12.30 on Tuesday, October 6th, 1908.

History.

Directly after defaecation about 9 a.m. on the previous Sunday, pain in the central and lower parts of the abdomen came on, and continued. It was paroxysmal and severe. Vomiting commenced the same evening, and had been frequent from that time. The vomit consisted of bile and watery fluid. No flatus had been passed since the onset of the pain, and only a very little hard motion had come away after an enema, and nothing after the administration of purgatives.

Condition on Examination.

The abdomen was moderately distended, and slightly tender just to right and below umbilicus, but not rigid. There was marked intestinal splashing. Nothing made out on rectal examination. No distended coils were seen. There was no history of any previous attacks. Dr. Burroughs told me he had not found his temperature raised above 99° at any time. Pulse was 88 and good strength. There was no external hernia. The symptoms of acute intestinal obstruction (mechanical) were thus obvious and the need for coeliotomy clear.

Operation.

He was admitted to the General Hospital in the afternoon, and operated at 4 p.m. On opening the peritoneal cavity considerable amount of blood-stained fluid escaped. The last two feet of the ileum were empty, but all the rest of the small intestine was red and greatly distended. On tracing the empty bowel I found it passed through a hole in some fixed structure, which from its position I thought must be the foramen of Winslow; but my incision did not allow me to see it. I drew out the intestine without much difficulty, and found I had withdrawn the junction of empty and distended gut, and on the latter was a groove of constriction.

The distension of the small intestine was so great I did not like to trust to spontaneous evacuation. I tried first to force on the contents through the empty coil into the large bowel, but could make very little progress. So I clamped off a few inches and tied on a very small Paul's tube. Through this, by a kind of "milking" of coil after coil outside the abdominal cavity, I was able to evacuate the intestinal contents in a moderate time, and replace the intestine within the abdomen in a nearly empty condition. The coils of intestine whilst outside the abdominal cavity were as far as possible covered with a sterile towel wrung out of quite hot saline solution. I finally fixed the portion of bowel into which the Paul's tube was inserted to the parietal peritoneum by several fine thread sutures, and closed the abdominal wound around it. A very thin rubber tube conveyed intestinal contents from the Paul's tube into a bottle. The pulse ran up to 140 during the operation and remained at that at the end, but it was a pulse of fair volume and strength.

After-history.

On the following day, October 7th, my note says that there had been no vomiting since the operation, but even anaesthetic vomiting, and that his abdominal pain had ceased. Some liquid faeces had been discharged through the tube. His pulse was good. Some moderate distension, with slight abdominal tenderness, was present. On the 8th his condition was much

the same. On the 9th he had much pain in the right loin, removed by a grain morphine. There was no vomiting, and his pulse kept good. On the 11th the abdomen was flat and not tender. On this date I noticed that his Paul's tube had not separated, but at one spot the parietal peritoneum, where it had been sewn to the bowel around the inserted tube, had become sloughed and left a funnel-like opening into the peritoneal cavity—that is, amongst some coils of intestines. This space seemed well shut off by intraperitoneal adhesions. However, I packed it with a little iodoform gauze. On the 12th the Paul's tube began to separate and was removed. The bowels were acting freely through the artificial opening and slightly per anum. On the morning of the 13th the patient complained of pain in the lower abdomen. There was no vomiting. He did not complain of this later in the day, and his pulse kept good. In the evening he was reading the newspaper. There was no pyrexia. But at 10 p.m. the night nurse noticed he was lying partly uncovered, and he must have looked worse, for she felt his pulse and found it very bad; and by 3 a.m. he was dead. It was almost like a sudden death, in a man apparently doing fairly well.

Necropsy.

The *post-mortem* examination showed that the union of the open bowel in the wound to the parietal peritoneum was easily broken down, and that leaking had occurred at the funnel-shaped opening referred to in my note of the 11th. The intraperitoneal adhesion around this had not been firm, and infection of the pelvic peritoneum had taken place. There was a little lymph on a few coils of bowel around this, and an extensive pelvic peritonitis extending from it, but the rest of the peritoneal cavity was free from inflammation. The heart muscle was not degenerated, nor was there any other form of cardiac disease. It was evident that the intestine must have been strangulated in the foramen of Winslow, for there was no other opening in which it could have been gripped. A careful search was made for such openings in the region of the duodeno-jejunal junction and elsewhere. The foramen of Winslow easily admitted one large finger—that is, it was about the usual size, but very often it is hardly open, as it was in this case, and is more of a slit, and in some cases it is closed by adhesion. In some of the cases of hernia into the foramen of Winslow some abnormality of the mesocolon or mesentery has been observed. Nothing of this kind was noticed in this case, but I did notice that it seemed quite easy for the small intestine to reach the oramen; possibly the mesentery may have been unduly long.

The most recent and exhaustive account of retroperitoneal hernia with which I am acquainted is in Mr. Moynihan's book on the subject, the second edition of which was published in 1906. In Sir F. Treves's work on intestinal obstruction you will also find very interesting information on the subject. As you can consult both these works, I will only very briefly refer to the subject.

Either the large or small intestine may be herniated through the foramen of Winslow, and when it has passed into the lesser sac of the peritoneum it may pass out through a rent in its wall, either the gastro-hepatic omentum or the transverse mesocolon, and in one case it was strangulated not by the foramen of Winslow, but by the rent in the transverse mesocolon. The symptoms are those of any form of strangulation of the intestine, with possibly the addition of a resonant swelling in the upper abdomen if a large amount of bowel is herniated into the lesser cavity of the peritoneum. In one recorded case the symptoms were those of subacute obstruction, the gut not being strangulated. Curiously enough, in this case it was impossible at the operation to reduce the large amount of intestine which had passed through the ring, but spontaneous reduction occurred soon after. That has been the difficulty in many of the cases of strangulation. It was so in Treves's own case. The ring is bounded by such important structures that it cannot be divided. Moynihan suggests that the difficulty of reduction may be due to the formation of a volvulus within the lesser sac of the peritoneum, and advises that a free opening into the sac shall be made through the gastro-hepatic or gastro-colic omentum, and that any volvulus should then be untwisted, and, if that is not enough to enable the surgeon to reduce the hernia, that the distended coils should be opened and their contents evacuated, and the opening sutured. Fortunately, in my case there was not the slightest difficulty in withdrawing the small strangulated coil of bowel. The only case of recovery after operation for strangulation in the foramen of Winslow is Delkeskamp's case.¹ The hernia was a very large one, and consisted of both colon and small intestine. The lesser sac was freely opened, and the contents of the herniated colon was expressed into the colon outside the ring, and thus it was possible to reduce the hernia.

As I have already stated, I noticed nothing abnormal about the intestines in my own case beyond the strangulation.

The foramen easily admitted a fairly large finger. In one recorded case there was a common ileo-caecal mesentery; in another the caecum was "undescented." The following conditions have been suggested by Moynihan as likely to allow of the hernia: (a) A common mesentery for the whole of the large intestine; (b) absence of the secondary fusion of the ascending colon to the posterior abdominal wall; (c) abnormally large size of the foramen of Winslow; (d) abnormal length of the mesentery and consequent undue mobility of the intestine.

In this case, when I had withdrawn the strangulated bowel from the hernial opening, I had removed the mechanical obstruction: and you may ask: Why was I not content with this? Why did I not leave the intestine to empty itself in the course of time? Probably it would not have emptied itself. The obstruction might have persisted though the mechanical obstruction of strangulation in the ring had been removed. When small intestine becomes greatly distended, it may fail to contract, because it is paralysed, and it may be unable to empty itself even if it can contract, because of the kinks in its course, due to the sharp curves of its over-distended, waterlogged coils. You must not think of distended small intestine as presenting gradual round curves along which the intestinal contents can easily pass, but of intestine with very sharp curves, with the coils pressed together, within the confined peritoneal cavity, by their own distension, and heavy with fluid contents. You will then understand why the gut may not be able to empty itself after the removal of such an obstruction as strangulation in a ring. Fortunately, in herniotomy, when the strangulating ring is divided and the bowel returned within the abdominal cavity, in the great majority of cases the bowel does empty itself, for operation is done before great distension has had time to come on, and, of course, in a case of internal strangulation, operated on early, there would be no need to empty the gut. But, if you relieve the obvious mechanical obstruction and leave greatly distended intestine within the abdomen, your operation may fail to relieve the patient. This is well recognized by surgeons. It may, however, be a difficult matter to decide how distended the intestines must be before we need empty them—that is, what condition of distension Nature can deal with. I will give you some details of a case under my care, some weeks before I operated on this case of hernia into the foramen of Winslow, which will impress on you the inability of Nature to deal with much-distended small intestine, due to such an obvious mechanical obstruction as strangulation under a band may cause.

The patient was a man 65 years of age, whom I saw in consultation with Dr. Cook and sent into the hospital and operated on on August 22nd last. I found the small intestine strangulated under a band, a short distance from the ileo-caecal junction, and the intestine on the proximal side of the obstruction considerably distended. However, it seemed to me at the time of the operation that the distension was not so great that the bowel could not slowly empty itself, and I therefore contented myself with pressing on some of the contents of the over-distended bowel into the empty coils, and did not make any opening for evacuation of intestinal contents. But faecal vomiting persisted and the distension increased. Twenty-four hours later I again opened the abdomen—as at the first operation mainly under stovaine spinal anaesthesia—and fixed a very small Paul's tube into the lower ileum, and almost emptied the intestines through this, in the same way that I did in the case of hernia into the foramen of Winslow. Even this did not relieve the symptoms, for next day offensive vomiting again recurred, and more distension than before. I removed the Paul's tube and passed a soft rubber tube as far up the gut as I could. This did not evacuate any intestinal contents, but a spontaneous evacuation of gas took place just after and the distension lessened.

I passed the stomach tube and removed 2 pints of what looked like bile, but was rather offensive. He did not vomit again, but no faecal discharge took place from the opening in the bowel for another forty-eight hours, and then the abdominal distension subsided; but by this time his strength had failed, and he died four days after the first operation. The *post-mortem* examination showed the upper jejunal coils still very greatly distended. The more

distal coils down to the original seat of strangulation were very dark and loosely adherent.

You very likely think that, if a case of mechanical obstruction of the bowel is operated on, the obstruction removed, and the bowel, if strangulated, is not too severely damaged to recover, the patient will do well, provided he has strength to stand the shock of the operation. I wish it were so. One of the great terrors of the surgeon is great distension of the small intestine. One of the most experienced abdominal surgeons of the past taught us how hopeless it was to leave a patient with greatly distended intestines, even though a mechanical obstruction had been removed. How best to deal with that greatly distended intestine is the problem which I have very anxiously considered, and about which I have something further to say. First, however, let me give you another example of the difficulties you may meet with in the treatment of this condition.

A boy, 12 years of age, was sent to me by Dr. F. Peake at this hospital on March 7th, 1902, with a greatly distended abdomen. I operated at once, and found all the coils of small intestine red and greatly distended, and removed a perforated appendix, and evacuated an abscess in connexion with it. The suppuration was quite localized. As the distension increased after this operation, I opened the abdomen again forty-eight hours later, and found there was a definite mechanical obstruction from matting in the wall of the abscess. Greatly distended and empty bowel joined in the matted segment. I released the adherent coils, and then evacuated the distended intestine, as I did in the case of hernia into the foramen of Winslow, but I did not use a Paul's tube, but evacuated the intestinal contents through a minute incision which I afterwards sewed up. The next day the distension was again very great. I applied cocaine to the sewn-up wound, removed some stitches, sutured a distended coil lying beneath to the skin, and punctured it with an aspirating trocar cannula. One rush of gas occurred, but nothing further, and the distension persisted. Nothing further escaped even after an interval. Clearly only one coil had been emptied up to the next kink above it. The boy died, and the *post-mortem* examination showed that this was so. It also showed that no mechanical obstruction persisted other than the kinks in the distended coils.

Although it is generally agreed that greatly distended small intestine cannot always—perhaps generally—empty itself, yet it has been frequently urged that the right thing to do is to make an opening in the distended bowel through which it may gradually empty itself—to fix a coil in some way in the abdominal wound and drain it. But what can we expect to gain by this? If the bowel is paralysed and kinked, and therefore cannot empty itself, how are you going to overcome these difficulties by making an artificial opening in it? The only way in which it is conceivable such an opening could help would be this. The empty coils within the abdomen, into which the contents of the over-distended ones would have to be discharged, would be under pressure within the peritoneal cavity, and it might not be as easy for the over-full coils to empty into them as through a direct external opening.

But there is a fallacy here. By making an external opening you may immediately empty one or two coils (probably only one): now that empty coil also lies within the abdomen subject to the pressure of the surrounding over-distended coils confined within the abdominal cavity, just as the empty coils below the seat of removed obstruction do, and it will therefore be as difficult for the distended bowel to empty itself into the coil as into the empty ones below the level of obstruction.

But if you have a direct external opening, what reason have you to expect that the partly paralysed and kinked gut will be able to empty itself through it? In one case I have related to you I brought a distended coil to the surface and opened it, and gas came out with a rush and the distended coil collapsed, but the coils above remained over-full and kinked just as if I had made no external opening at all. Again and again I have turned greatly distended coils of small intestine out of the abdomen, and opened a coil, but one never sees the one opening empty more than the one coil, up to the next kink above it. Yes, but you may say, you cannot expect coils of intestine protruded from the peritoneal cavity, even if covered up by a towel wrung out of hot saline solution, to contract and

empty themselves coil above coil, as they might do within the abdomen when anaesthesia has ceased. But even within the abdomen, I know from experience, they may not be able to empty themselves. Think of the pressure to which all those distended coils are subjected within the abdomen; how tightly they will be packed together, how waterlogged and kinked they will be—the more kinked the tighter they are packed together within the abdomen. If you try to return prolapsed, greatly distended coils within the abdomen you will then realize the tightness of this intraperitoneal packing. If you wish to make sure of getting your over-distended intestine empty (or nearly so) there is only one way of doing that, and that is to empty it yourself. You must turn the distended coils out of the abdomen, cover them with frequently-changed sterile towels wrung out of hot saline solution, make an opening in the distal end of the distended bowel, and then by passing the whole length of the intestine through your thumb and finger, empty it coil after coil. You must not begin at the proximal end or you will get too much fluid concentrated into the middle coils. You must first empty several coils near the artificial opening, and then work from nearer the proximal end into these. Finally you start at the proximal end and work all along to the opening. It is by no means easy to anything like empty the gut, though it is easy to get away a great quantity of fluid and gas. There is a constant tendency for the contents to escape your finger pressure and to pass backwards. It is therefore well to follow up the evacuating thumb and finger of one hand by the thumb and finger of another used as a sort of travelling clamp, or an assistant can take this part of the work. Rubber gloves, instead of being a hindrance, are really a help in evacuating the gut in this way—"milking the gut," as it is sometimes called—for they let the bowel slip through without the slightest friction. I have tried forcing the contents of the distended coils into the empty (and usually contracted) coils. It is easy to fill these up, and perhaps in time one might succeed in forcing the contents of the distended coils on through them into the large intestine, which could then be stimulated to empty itself by the administration of a hot turpentine enema. But it is a very slow and imperfect method, and I have never been able to get a sufficiently satisfactory evacuation of the distended intestine in a reasonable time by it.

But unfortunately all this manipulation of the gut is just the very thing most likely to bring on shock; indeed, the turning out of the intestine alone is likely to do this. We may then return the intestines empty within the abdomen, but the patient may speedily die from shock. If the patient is in a condition of collapse at the time of the operation, it is, it seems to me, useless to attempt it, for we shall only hasten the end by the shock produced. But if the pulse is fairly good I think it is the right thing to do. That it is the only way in which we can satisfactorily deal with greatly distended, partly paralysed, and kinked small intestine, I feel convinced, and I pointed this out in a letter which I published in the *Lancet* of April 11th, 1903. If you have greatly distended large intestine, every one knows it is quite enough to make an artificial opening, and it will empty itself. It does not lie in a series of loops which form kink after kink when over-distended and subjected to pressure. However distended the colon may be behind a mechanical obstruction, if you make an artificial opening it will empty itself in a reasonable time, and generally very quickly. This makes me sceptical whether over-distended small intestine is really paralysed, or even partially; whether it is not wholly a question of kinking at its flexures.

I have in this lecture spoken of it as paralysed, for this is the generally received view, and we might expect intestine as obviously congested as such distended intestine almost always is, to have its muscle contraction somewhat interfered with, at any rate. And when we do colotomy for a growth in the sigmoid, we must remember that the process has been slow, and there has been time for hypertrophy of the muscle of the colon to take place. Still, I must say it seems to me that if great distension can so little paralyse the large bowel, it is a question whether it can to any extent the small.

I have so far said nothing about the kind of opening that should be made in the bowel for the purpose of evacuating its contents. This must be so arranged that

there will be a minimum risk of soiling the peritoneum. I used to get an assistant to take a coil of bowel, and hold it over a basin well away from the other coils, isolate it and his hands with a towel, nick the gut, and let the contents flow out, then clean it up, and sew up the opening. I now adopt what I think is a safer method. I clamp a few inches of gut, and fix into this a very small Paul's tube, less than $\frac{1}{2}$ in. in diameter. To this tube several feet of very soft light rubber tubing, as thick as the rubber of an operating glove, is attached, and, as all the intestinal contents are conveyed through this to a receptacle removed from the area of operation, there is no risk of infecting the intestines, provided the gut and the hands are cleaned well after inserting the Paul's tube. A Carwardine's tube could, of course, be used for the same purpose if it was determined to remove it at the end of the evacuation and close the opening, but I prefer Paul's tube myself. But it seems to me a question whether one is wise in closing the opening. The condition of the intestinal wall is not the best for repair, and the stitching will take up time at the end of an operation already too long for the patient. My own feeling at the present time is that it is perhaps better to leave in the Paul's tube, and sew the coil to the parietal peritoneum in closing the wound. The faecal fistula thus formed ought to close before long with no mechanical obstruction on the distal side of it. If, however, the distension of coils only involved the upper portion of the small intestine, and the opening had to be near the middle, I should not make a faecal fistula so high, but would rather take the risk of leakage at my junction, and remove the Paul's tube and sew up the opening. Unfortunately in the case which I have made the subject of this lecture, even fixing the gut to the parietal peritoneum did not lead to a firm union at the end of several days, and leakage into the peritoneal cavity occurred. It was particularly disappointing, as the patient had really recovered from the obstruction.

We must realize that, given great intestinal distension in the small intestine in association with mechanical obstruction, the condition will be a very difficult one to deal with, and that its treatment will involve fresh perils, and that if the condition of the patient is such that obviously shock must be fatal, our chance of effectively dealing with it is small. I have not forgotten the use of spinal anaesthesia by stovaine in such cases. Anaesthesia of the upper abdomen by this method is always uncertain. It has seemed to me in some of my own cases of operation within the abdomen to prevent shock, and also in reports I have read of others (Mr. Barker's and others); yet it seems as if it did not wholly abolish shock in all cases, for I have been told by some one watching the pulse in some cases during my operation that it has shown signs of failure when I have been dragging on the abdominal viscera, though the patient felt no pain. How this can be I must leave the physiologists to explain. If the spinal cord is absolutely locked to sensory impulse, how can any impulse be conveyed to the vasomotor centre in the medulla, which would paralyse that centre? I think it will be wise to use stovaine spinal anaesthesia in these cases of marked distension and bad pulse, if the pulse is not so desperately bad as to make such an operation unwise, for even if it only acts on the lower two-thirds of the abdomen it may do very much to reduce shock in evacuating the intestine, even though a little general anaesthetic is required as well. In one of the cases related to you to-day you may remember I used it, but a little general anaesthetic was required as well. There was no serious shock in this case, though manipulation of intestine was considerable.

I have said that I think the only satisfactory way of dealing with the greatly distended, kinked, (?) paralysed bowel is to empty it at the time of operation. But alas! this is not always successful, even when it does not induce fatal shock. I have given you two instances in which the great distension present before such evacuation returned directly after, and vomiting also returned. Why should this be so? It may be that the manipulation of the gut sets up a very mild peritonitis (non-septic), and that to this is due the secondary distension. Adhesive peritonitis was found in both the cases, that is, a degree of peritoneal inflammation causing adhesion but no lymph or pus exudation. This condition was quite marked in the case of the elderly man who had had strangulation, but my

note of the boy only says that "the coils of small intestine had a tendency to adhere together."

The difficulties, then, with which the surgeon has to contend in dealing with the greatly distended small intestine are many. If he only makes an external opening, the kinked and (?) paralysed bowel may not empty itself; and if he empties it at the time of the operation, his manipulations may lead to fatal shock; or, if they do not, the intestine may soon fill up with gas and the obstruction continue. In the face of all this discouragement, what is the lesson to be learnt? I think it is the absolute importance of operating early before great distension can set in, and of operating in acute appendicitis before mechanical obstruction from matting around the diseased appendix can occur. One surgeon of large experience in abdominal surgery has recently written: "The surgery of acute obstruction is disheartening work," and that the mortality is far larger than it ought to be owing to delay in operation.

I have been speaking about greatly distended small intestine in mechanical obstruction. If due to peritonitis, I think the treatment must be the same and the risks will be the same. The uselessness of simply making an opening in a distended coil and expecting all the other over-distended coils to empty themselves through it, seems, if anything, more evident when the whole bowel is inflamed than when it is not.

I do not wish you to think that I consider that it is useless to open distended small intestine without oneself emptying the bowel by a manipulation in every case. It depends on the degree of the distension. There are some cases of mechanical obstruction in which this is the right thing to do. Not long ago I had to do colotomy for a large, fixed, irremovable cancer of the lower colon, and a few months later the man got further obstruction from fixation of small intestine to the mass. In this case, knowing I could not deal with the cause of the obstruction, I brought out a coil of small intestine and fixed a very small Paul's tube in it, and relieved the obstruction in this way. But, if this man's small intestines had been enormously distended and kinked, I do not believe they would have discharged their contents through the opening.

There is just one other matter to which I should like to call your attention. Some surgeons have recommended that we should empty the distended coils by pushing a long rubber tube into them, through the incision made for drainage (I am not now speaking of the method advocated by one surgeon of drawing many feet of small intestine on to a glass tube at the time the intestines are all exposed during the operation); but how can he expect to succeed in passing such a tube through coil after coil of kinked, overlaid small intestine? It is interesting that the recommendation has been made, because it implies the recognition of the fact that simply to open distended small intestine may not be sufficient to drain it. But I have proved in the *post-mortem* room how, instead of passing from coil to coil, the rubber tube simply coils up when it meets with the obstruction of the bend, as one might expect. You may think it curious that, if I have no faith in the use of a rubber tube, I should actually have used it in one of the cases I have recorded. I only used it to clear the coil just beyond the opening and had no hope of its doing more.

THE AFTER-RESULTS IN A SERIES OF OPERATIONS FOR THE RADICAL CURE OF HERNIA.

By R. W. MURRAY, F.R.C.S.,

SURGEON, DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.

FOR some years I have paid particular attention to the subject of hernia, especially in regard to its etiology, and the more I study the question the stronger is my belief that the essential cause of all ordinary abdominal herniae is a congenital defect, the presence of a peritoneal diverticulum.

In several communications I have advanced evidence in favour of the sacular theory of hernia. I have pointed out how the same types of sac are met with in the infant and in

the adult, how clear the distinction is between the sac of a congenital and that of a traumatic abdominal hernia, and how impossible it is in the case of an inguinal hernia in an adult to distinguish between the so-called "acquired" and the congenital sac.

I have also considered the question from the point of view of comparative surgery; but perhaps the strongest point I have hitherto made in favour of the sacular theory was that, in 200 consecutive *post-mortem* examinations made upon persons in whom during life there was no history or evidence of hernia, in 47 bodies 68 peritoneal diverticula were found either in the inguinal, femoral, or umbilical regions. In many cases the diverticula were bilateral, and in one case occupied both femoral and both inguinal canals.

I now propose to bring forward clinical evidence in favour of the congenital origin of hernia by directing attention to the after-results in a series of operations performed for the radical cure of hernia upon persons whose ages varied from 1 month to 72 years. I have selected the years 1905-6-7 because during that time I adopted the same principle in operating, and also because the cases have now undergone a fair time test. I do not say all these cases are certainly cured, but as over 80 per cent. of recurrences take place during the first twelve months following operation, it is reasonable to believe that the vast majority of these persons have been permanently cured.

The figures include every case of hernia I operated upon during that period, whether in hospital or in private practice, except cases in which the bowel was strangulated.

I have been at considerable pains to ascertain the after-results, and as this is the chief point in the present communication I may say that any bulging at the site of operation was regarded as a recurrence; and, further, that in almost every instance the examination of the patient was made in the presence of other medical men.

In the accompanying tables (p. 645) I have grouped the cases according to the age of the patients at the date of the operation, and it is at once seen that up to middle life the probabilities of a complete and permanent cure are considerable.

As to children under 10 years of age, it is now so generally recognized that a radical cure follows complete removal of the sac that it is unnecessary for me to dwell upon the results obtained in this series, except to draw attention to the mortality, which, I regret to say, has been far too high.

One child, 4 months old, was operated upon in the summer of 1905, and died a week later from diarrhoea.

Another child, 2 years old, died two days after operation from delayed chloroform poisoning.

The third case, a child of 3 months, died suddenly and altogether unexpectedly two days after operation. No definite cause for the child's death could be discovered at the necropsy.

Although these deaths should certainly be attributed to the operation, still I am glad to be able to say that in no case was there anything wrong with the wound.

METHOD OF OPERATING.

As in the case of the adult patients the operations performed for inguinal, femoral, and umbilical hernia differ in some important respects from those generally adopted, I will describe them under the several varieties of hernia.

Inguinal Hernia.

Everybody is agreed, and for a great many years everybody has been agreed, that it is very important to completely remove the sac, and I have not the least doubt that any and every surgeon who has ever operated for the radical cure of inguinal hernia is perfectly satisfied that he did completely remove the sac. I very much doubt it. This is a matter of very great importance, for I am quite sure that the chief cause of failure after operation is incomplete removal of the sac. In examining patients in whom hernia has recurred I have been at once impressed by the position of the scar. The skin incision had been made far too low—in fact, it encroached upon the scrotum, and did not extend upwards further than the external abdominal ring. Through such an incision it is impossible to excise the sac completely. The lower end of the skin incision should not extend more than $\frac{1}{2}$ in. below the

The After-Results in a Series of Operations for the Radical Cure of Hernia Performed during the Years 1905, 1906, and 1907, considered according to the Age of the Patients at the Date of Operation.

Hernia.	Cases.	Satisfactory 12 Months and over after Operation.	Unaccounted for.	Relapsed.	Died.
Boys and girls under 10 years of age:

Direct inguinal... ..	2	2	—	—	—

external abdominal ring. I always open up the inguinal canal for about $1\frac{1}{2}$ in., and, having found and isolated the sac, make a point of pulling it vertically upwards, and at the same time brushing back with gauze the vas and other structures clinging to the neck of the sac. I continue to pull the sac upwards and push back the surrounding structures until I bring into view a marked thickening of the peritoneum. This thickening is to be found on the pubic side. I always look for it, and when it appears know I have reached the limits of the sac. By transfixing and tying the peritoneum through this thickened portion the limits of the sac have been passed, and when it is cut away the ligatured stump at once disappears from view beneath the internal oblique. This thickening of the peritoneum is physiological. It is present during infancy as well as during adult life, and when operating for inguinal hernia should always be looked for, as it is the only true indication the limits of the sac have been reached.

The sac being thus completely removed, I unite the divided aponeurosis of the inguinal canal. Formerly, I did this by overlapping, but more recently I have taken a double hold of the aponeurosis on either side with the needle, and so, with four or five stitches narrowed and

lengthened the inguinal canal. The cord is not interfered with, and, after tying several small blood vessels, the skin incision is closed.

On the seventh day the subcutaneous wire or stitches are removed, and, as a general rule, the patient is allowed to get up on the tenth day, and leaves the hospital on the fourteenth day, after the operation, not wearing a truss or support of any kind. He is advised not to return to work until at least two more weeks have elapsed. I formerly kept patients in bed for two weeks after operation, but by getting them up sooner I have added to their comfort and in no way retarded their recovery.

Such has been the routine treatment for inguinal hernia, and when it is remembered that my list includes all sorts and conditions of men—some young, healthy, and favourable subjects, others weather-beaten, beer-worn creatures, who for years had a large scrotal hernia containing omentum, it is extremely gratifying to me to find results so satisfactory following upon such a simple method of operating.

I would draw particular attention to the list of men under 40 years of age. Most of them were dock labourers, carters, or sailors, and many had been ruptured for years. From the time of operation they were off duty about six or eight weeks, and since resuming work have remained sound and well, not wearing a truss or support of any kind. It is really very encouraging not to have had a recurrence in any man or woman under 40 years of age; and the fact that this result has been obtained by an operation which aims at little more than the complete removal of the sac, is additional and substantial evidence in favour of the view that the presence of the sac is the essential cause of the hernia. It also emphasizes the point that, provided the whole sac is removed, it is not necessary to spend time and trouble in what is called "strengthening" the abdominal wall by transplanting the cord, or by adopting other more or less complicated measures. In the case of men over 40 years of age exactly the same method of operating was practised, but in such persons a permanent cure cannot be looked for with the same confidence as when the operation is performed earlier in life.

Many of these cases were men over 50 years of age; and would have been considered unfavourable for operation by any surgeon, some of them perhaps altogether unsuitable, owing to the age of the patient, the size of the hernia, and the length of time it had been present. However, the results are, on the whole, satisfactory, in spite of the fact that in three cases the hernia relapsed, and in one case death followed upon the operation.

Of the three cases that relapsed; two were 58 years of age at the time of operation, one suffered from a double scrotal hernia of some years' duration, the other man had a large inguinal hernia, for which he had worn a truss for twenty-nine years. Both these patients now have a distinct bulging at the site of operation, but a truss is worn with much greater comfort than before operation. The third case of failure occurred in a man aged 41, operated upon in 1906. Some months after he left the hospital. I heard indirectly that he was in hospital in Singapore on account of a rupture, but I am not quite sure whether it was a relapse or a hernia on the other side.

The case of the man who died was somewhat remarkable:

He was 58 years of age, and operated upon for inguinal hernia. All went well, the wound healed, and the man got up at the end of two weeks, but returned to bed owing to an attack of bronchitis. Four weeks after operation he was to leave the hospital, and was dressing himself when he had a sudden and remarkable seizure and died in a few minutes. At the necropsy no definite cause could be discovered to account for his sudden death.

Though I cannot directly attribute the man's death to the operation, still, as he died in hospital after operation, it is better to consider his death as in some way due to the operation.

Femoral Hernia.

All the cases of femoral hernia were operated upon in the same manner. A skin incision made over the sac and parallel to the fold of the groin exposes almost at once a structure frequently mistaken for the sac. It is not the sac, but a layer of fat concealing it, intimately attached to it, and, being enclosed by a thin fibrous membrane, closely resembles a thin hernia sac containing omentum. It should be thoroughly exposed

and isolated well up to the femoral ring; then, grasping it with one hand, I pull it outwards, at the same time brushing back with gauze the structures surrounding its neck. As a result of this firm but gentle pulling and pushing a marked alteration in the appearance of the fat surrounding the neck or mouth of the sac is noticed. At first it was of a reddish-yellow colour, but now it is pale yellow. This is due to the sac and surrounding fat being pulled outwards and the subperitoneal fat beyond the mouth of the sac exposed to view. I always continue to pull outwards and push backwards until the pale yellow subperitoneal fat is exposed, for the limits of the sac have thus been determined and a suitable level for applying the ligature reached. The fat surrounding the sac is now removed and a ligature applied at as high a level as possible. Nothing further is done except to close the skin incision. Complete removal of the sac, together with the fat surrounding it, is the essential feature of the operation.

I have never practised any of the more elaborate methods recommended for the radical cure of femoral hernia, and if, as would appear to be the case, a permanent cure can be brought about by little more than complete removal of the sac, surely this is strong testimony in favour of the view that in femoral as in inguinal hernia the presence of the sac is the essential cause of the hernia. Dr. A. J. Ochsner has used this method during a period of fourteen years, and is convinced that, barring unusual accidents, recurrence is out of the question provided the operation is properly performed. He has been able to get definite reports and to examine 30 cases of femoral hernia. In no case was there a recurrence.

Umbilical Hernia.

In every case the method of operating first described by W. J. Mayo was adopted. The hernial protrusion is included in two transverse elliptical incisions, clearly exposing the neck of the sac and the aponeurotic structures above and below it for several inches. The sac is then opened at its mouth, and any intestine which may lie in it returned into the abdomen. The contained omentum, usually adherent, is ligatured in sections and returned into the peritoneal cavity. The sac with all the adherent omentum, including the skin, is cut away. The entire thickness of the aponeurotic and peritoneal surfaces are then united by overlapping from above downwards. By adopting this plan the operation for the radical cure of umbilical hernia is much more simple than it used to be when the vertical incision and side to side union was practised and the after-results far more satisfactory than they ever were or could have been after the older methods. The operation is often formidable owing to the size of the hernia and the enormous abdominal girth of the patient. My six cases in women over 40 years of age were all very stout, one patient weighing 18st.

CONCLUSION.

It has often struck me as being somewhat discreditable to the science and art of surgery that for the cure of such a common complaint as inguinal or femoral hernia there should be so many operative procedures differing widely in principle. Clearness of purpose and simplicity in method should be our aim, and if results such as I have the pleasure in recording can be obtained by an operation which essentially and almost entirely consists in the complete removal of the sac, this surely is strong evidence in favour of the sac being the essential cause of the hernia, and is also an encouragement to surgeons to simplify their methods when operating, to pay less attention to repairing the abdominal wall, and more attention to the complete removal of the sac.

THE *Polietinico* has published a first list of members of the medical profession who perished in the earthquake at Messina. Among them are the following: Dr. Gaspare D'Urso, professor of clinical surgery; Dr. Antonio Zincone, professor of anatomy; Dr. Agatino Giovanni Barbera, professor of physiology; Dr. Giovanni Melle, professor of dermatology and syphilis; Dr. Antonio Cambria, lecturer on clinical pathology; Dr. Francesco Fonzi, lecturer on materia medica; and Dr. Carmelo Calderone, lecturer on dermatology and syphilis—all of the University of Messina; Dr. Tullio Mazzei, director of the Antinatal Institute; and Dr. Lorenzo Mandalari, lecturer on mental diseases in the Medical Faculty of Naples.

STRANGULATED HERNIA THROUGH THE FORAMEN OF WINSLOW: OPERATION: RECOVERY.

By THOMAS SINCLAIR, M.D., F.R.C.S. ENG.,
PROFESSOR OF SURGERY, QUEEN'S COLLEGE, BELFAST.

THE occurrence of this form of internal hernia is sufficiently rare to justify the publication of the details of a recent successful operation. About 20 cases have hitherto been recorded since the first described by Blandin in 1823. Many of these were only recognized after death, and are therefore of interest mainly in reference to the morbid anatomy of the parts concerned. Seldom has the diagnosis been determined in life before operation as in the present instance, and it may therefore be of interest to state briefly the leading symptoms in this case.

In the example here described the diagnosis of this obscure form of internal hernia was made by Dr. Tate, Surgeon to the County Infirmary, Downpatrick, to whom I am indebted for the description of the earlier symptoms, as well as for his skilful assistance during the operation involved.

The patient was a gentleman aged 58 years, in excellent general health, who had been out shooting the previous day. No other intestinal trouble had ever been experienced, and he was accustomed to have a regular daily evacuation from the bowels.

History of Illness.

He had a sharp turn of coughing on rising on the morning of December 13th, and when shaving shortly afterwards was seized with violent pain in the upper part of the abdomen, the lower part of the chest, and the back. It was colicky and gripping in character and radiated into the interscapular region, and there was some retching. A reaction of the bowels followed at once upon this seizure. This emptied the lower bowel, but without relief to the pain. The patient then took Hunyadi Janos water, without result. Copious turpentine injections and further aperients, including calomel, failed. The constipation was absolute for faeces and flatus. His pulse was 70, and the temperature normal. Vomiting was neither frequent nor severe, being wholly absent on the third day of the illness, but hiccough supervened on that day. There was no rigidity of the abdominal wall, and no distension for the first two days, and it could not be said that any definite epigastric swelling existed. On the morning of the operation an ill-defined fullness, free from tenderness, began to show itself in this region. The temperature and pulse at this stage did not exceed 99.50 and 76 respectively. During the paroxysmal exacerbations of the pain, which was referred to the interscapular region and to the lower part of the thorax and epigastrium, the patient found most relief by turning on his face and pressing with his hand on the upper part of the abdomen. There was no pain in the umbilical region or below it at any time.

Operation.

Coeliotomy was performed on the third day, the abdomen being opened by an incision above the umbilicus in the middle line. The margin of the foramen of Winslow tightly constricted the gut, and was treated by gentle dilatation sufficiently to allow the constricted portion to be withdrawn. Two and a half feet of jejunum were withdrawn from the smaller sac of the peritoneum with comparative ease. The annular constriction was sharply defined and almost gangrenous, and the gut felt as if only the outer tunic of the gut remained. It was decided not to excise the damaged portion, but it was brought to the parietal wound and ultimately fixed behind it by two catgut sutures. The free border of the great omentum was carried round it, and fixed by sutures to it, and to the mesentery by several points of suture on either side, thus forming a loose protective sleeve, in order that, if perforation or rupture occurred, the extravasation might happily be retained in an omental compartment opposite the parietal wound. No abdominal complications arose, and the patient was about again within three weeks.

It may be remarked that of the 18 cases collected by Jeanbrau and Riche, coeliotomy was performed in 11 cases, with 4 cures. The same observers, after a series of experiments upon the cadaver, state their belief that the foramen of Winslow can be safely enlarged by an incision made through the peritoneum forming the anterior lamina of the gastro-hepatic omentum at the upper border of the first part of the duodenum (*Keen's Surgery*).

In this case, however, no incision was made, but a cautious dilatation of the foramen was practised with the tip of the little finger.

Certain points seem worthy of emphasis: (1) Notwithstanding the tight constriction, reflex vomiting was not an urgent symptom—which is all the more remarkable, when only $\frac{1}{2}$ grain of morphia was given hypodermically throughout the three days that the strangulation lasted; (2) the pain

in the interscapular region; (3) the instinctive adoption of the prone position, with leaning forward, to relieve the epigastric pain; (4) the absence of pain around the umbilicus and below it.

A CASE IN WHICH ENTEROSPASM WAS A PRONOUNCED FEATURE, NECESSITATING ABDOMINAL SECTION FOUR TIMES WITHIN TEN MONTHS.

By C. W. DEAN, F.R.C.S.E.,

HONORARY SURGEON, THE ROYAL LANCASTER INFIRMARY.

UNTIL I read Dr. Ashe's most interesting account of his case of enterospasm, in the *BRITISH MEDICAL JOURNAL* of March 2nd, 1907, I, like him, was ignorant of this condition as a recognized pathological state. As it was, the perusal of his paper and the clear and concise description of the symptoms and of the conditions found at the subsequent operation enabled me some months later to solve, without leaving much room for doubt, what otherwise would have been a difficult problem; and although the treatment adopted in my case of necessity differed from that followed in his, still the picture disclosed in the case I am about to describe at once told me that I was looking at a piece of intestine in a state of tetanic spasm, a sight I had never before beheld.

Since reading Dr. Ashe's paper, Dr. Herbert P. Hawkins has most kindly sent me a reprint of his commentary on *The Reality of Enterospasm and its Mimicry of Appendicitis*, which appeared in the *JOURNAL* of January 13th, 1906. This most able paper tells us practically all that is known up to the present time of spasm of the intestine and enteralgia—two conditions which seem to accompany each other in all the recorded cases. In Dr. Hawkins's paper one sentence specially impressed me as being pregnant with truth—how true no one can appreciate until he has been many years in practice; that is, "there is much abdominal pain which has no name and does not kill."

How often has the abdomen been opened for acute symptoms simulating gastric ulcer or obstruction, symptoms which were perhaps not classical, which did not quite fit in as they should with the description given in the textbooks, but which were too alarming apparently to admit of delay, in which laparotomy has been performed, and yet nothing has been found subsequently to justify the operation?

I know this has happened to me, and it must have occurred over and over again in the experience of other surgeons; but cases like these are not recorded—may they not in many instances come under the category of acute enterospasm? I venture to think so.

The notes of the following case may possibly be of some interest, for these reasons: laparotomy was performed four times in less than ten months, a cyst of the ovary was removed at one operation, enterotomy performed at another, 4 in. of small intestine removed at the third, and 7 in. of small bowel were resected at the fourth. The crowning point of the whole thing is that the patient is now in excellent health and expresses herself as "feeling better than she has done for years." On reading this account casually some people may be inclined to think that the aid of surgery may have been invoked perhaps somewhat too hastily, but I can assure them that such has not been the case in this instance.

The late Dr. W. Croft Helme, a man of much experience and knowledge, under whose care the patient was, asked me to see the case with him in consultation to decide as to the advisability of operation. The symptoms on each occasion, in our opinion, presented features of extreme urgency. The final operation, of course, admitted of no delay, being due to the fact that the patient was suffering from acute obstruction. A point I think of much interest is the prominent part enterospasm played in the case, and the fact that the spastic bowel was seen and handled, and its condition deliberately noted, and so adding another instance to those already recorded.

History.

A young woman, aged 29, of a singularly placid disposition, has had three children, of whom two are living; her previous illnesses have been an attack of influenza every year for the past five years. For about four years she has had attacks of what she describes as cramp in the bowels, always attended by

vomiting and difficulty of defaecation. These attacks came on at any time without warning, while engaged in household work or while in bed. After the attacks passed off constipation always remained, sometimes for quite a long time. In addition there was constant pain in the left iliac region. In December, 1907, a lump was found in this situation, presumably in the left ovary, but its nature at the time was undetermined; in all probability, however, it accounted for the above-mentioned pain.

First Laparotomy.

On January 1st, 1908, the patient aborted at three months, and as she did not progress satisfactorily she was admitted into the Royal Lancaster Infirmary on January 14th under my late friend and colleague, Dr. W. Croft Helme. After she had been for five weeks under treatment, the tumour getting no smaller (I may say that there was a suspicion in Dr. Helme's mind of gonorrhoeal infection of the tube), I was invited to see her in consultation, and we came to the conclusion that we ought to open the abdomen; this we did on February 20th, and removed a rounded dark cyst of the ovary together with the tube, after having had to separate many adhesions. The tumour was examined by Dr. W. Gough, and showed the typical structure of a multilocular cystic adenoma. On the day after the operation she had pain in the abdomen, but of a severe cramp-like character, accompanied by vomiting and inability to pass flatus; enemata were given, but without any result. Dr. Helme feared the onset of septic peritonitis, but there was little or no distension, no rise of temperature, and the pulse was not unduly quickened; tenderness was general, but not marked, and the patient did not seem poisoned.

Second Laparotomy.

As the symptoms continued all the next day, Dr. Helme again asked me to see her, which I did on February 23rd, and advised reopening the abdomen, the general condition of the patient being so good and there being no sign of toxæmia. We operated in the evening of that day and found absolutely no trace of peritonitis; the site of the previous lesion was healthy, in fact at first sight everything seemed natural, but on examining more closely we found what looked like a piece of collapsed bowel, and on bringing it to the surface it proved to be a portion of the ileum near to its junction with the caecum, about 6 in. long, flattened, with slightly concave sides very like a piece of thin rubber tubing from which the air had been exhausted; each end joined the healthy gut by a sharp line, the spastic portion was paler than the rest of the gut, but beyond this there was no sign of disease, no distension of the upper end of the bowel and no marked congestion. Having read the account of Dr. Ashe's case, I had little difficulty in believing we had a similar condition to contend with. As the patient's state demanded relief and as, unlike Dr. Ashe's case, the bowel could not be induced to relax, I opened the gut just above the contraction. The patient was much relieved and soon recovered perfectly, with the exception of the inconvenience caused by the enterotomy wound, and had no return of the spasm.

Third Laparotomy.

On April 2nd, six weeks after the second operation, we wished to close the opening by a plastic operation, but as the wound had stretched so much this was found to be impossible, so the abdomen was again opened and some 4 in. of bowel removed and the ends joined by a simple suture.

From this third operation the patient recovered without a bad symptom, a natural motion being passed on the third day. She remained in hospital until May 16th, when she went home and resumed her household duties. She had some little trouble with a stitch abscess, but beyond that she got on very well. She now tells me, however, that she was never free from a slight feeling of abdominal discomfort.

Fourth Laparotomy.

On December 7th, 1908, she sent for me late in the afternoon (my friend Dr. Helme had died during the previous September) saying she was ill again like she was before. I found her in bed with her legs drawn up, evidently suffering acute pain. She told me she was all right when she got up that morning, and had done her usual work until about 11 a.m., when while mangle some heavy clothes she felt a sudden pain in the abdomen; it had steadily got worse, coming on every now and then in spasms. She had vomited the contents of the stomach, and could not pass flatus. I of course thought of enterospasm as a probable cause of the trouble, but as the symptoms were so severe, and obstruction was evidently so complete, I advised her to come into hospital, telling her I might possibly have to open her abdomen again. She came in as soon as she could, and I saw her at 8 p.m. the same evening. The pain was now very severe and paroxysmal, and the whole abdomen exceedingly tender to touch and somewhat distended. She had again been sick, the vomit now being bilious in character, moreover she had not passed flatus in spite of the large enemata administered in the meantime. I determined to operate at once, and with the assistance of Dr. Parker I for the fourth time opened her abdomen. The cause of the mischief was at once found—a loop of small intestine was tightly strangulated by an adhesion which had formed after one of the previous operations; the loop was quite black, and had lost its lustre in places (distinct evidence of commencing gangrene can now be seen in the bottles and specimen). So for the second time within ten months I resected a portion of her bowel, this time about 7 inches, and united the ends by simple suture. From this operation she has perfectly recovered, as far as one can see. She declares she is quite well, and looks so; moreover, she has lost the feeling of discomfort she previously had.

THE DIAGNOSIS AND TREATMENT OF CHRONIC ULCER OF THE STOMACH AND DUODENUM.*

By ALEXIS THOMSON, F.R.C.S. EDIN.,

ASSISTANT SURGEON, ROYAL INFIRMARY, EDINBURGH.

NOTWITHSTANDING the number and excellence of the articles that have been written on this subject during the last few years, it does not seem that the profession as a whole has realized the practical importance of these affections, nor has it acquired the knowledge regarding them like that which it has attained, for example, in the diagnosis of lesions of the vermiform appendix. The difficulties are undoubtedly greater; when the appendix is diseased, it is always appendicitis in one form or another; when, on the other hand, there is a chronic affection of the stomach, there is a much wider field for mistakes, and a greater refinement of diagnosis is called for.

My contribution to the subject is the report of a consecutive series of 50 cases in which a chronic ulcer of the stomach or duodenum was not only diagnosed by clinical methods, but was demonstrated to those present at the operation undertaken for its relief. I may be said, therefore, to be speaking of facts and not of inferences.

The Site of the Ulcer.

The ulcer was situated in the pyloric ring or antrum in 16 (32 per cent.), on the lesser curvature in 12 (24 per cent.), and in the first part of the duodenum in 17 (34 per cent.). In the remaining 5 cases (10 per cent.) there was more than one ulcer, one of these being situated in the duodenum in all of them. This gives a total of 22 ulcers in the duodenum and 28 in the stomach. Bearing in mind that the so-called anterior wall of the pylorus and duodenum is really the right lateral wall, and that with which the acid contents of the stomach are first brought into contact, it is very striking that it is almost invariably the seat of the ulcer. It is true that ulcers on the posterior wall are more likely to escape recognition by the surgeon, because he is unwilling to extend or prolong the preliminary manipulations, but I am confident that the true proportion of anterior ulcers would be something like 95 per cent. When the ulcer is diffuse or affects both walls, the evidence goes to show that the disease commenced in the anterior wall. Ulcers of the lesser curvature specially tend to affect both walls, acquiring the saddle-shape first described by Mayo.

Sex.

There were 30 males (60 per cent.) and 20 females (40 per cent.). Ulcers affecting the stomach alone were equally divided between the sexes; the duodenal ulcers were distributed in the proportion of 18 males to 4 females.

Age.

The range was from 21 to 67 years, the average being 41; the age of the duodenal cases ranged from 25 to 67 years, with an average of 43. If the ages are corrected according to when the symptoms first appeared, the average age for the onset of gastric ulcer is 32 and for duodenal ulcer 38.

Duration and Remission of Symptoms.

The duration of the ulcer cannot always be determined with certainty, as in many cases there is an indefinite period of what is called ill health with indigestion before the onset of symptoms which may be regarded as due to ulcer. In the majority of cases there are periods of remission of weeks, months, and sometimes of years, during which the patient is actually or comparatively free from symptoms. These remissions are most marked in the cases of duodenal ulcer, and are sometimes quite as striking as those so commonly observed in affections of the gall bladder. The remissions tend to become shorter, and in many cases prior to application for treatment the suffering is practically constant.

Pain.

In 3 cases (6 per cent.) there was *no pain*; in one of these the ulcer involved the lesser curvature, the other

two the duodenum, but in all of them the ulcer was small, with little or no induration and a smooth peritoneal scar on the surface. In 3 cases there was *little or no pain*, and all of these involved the duodenum. In 8 cases there was more or less *constant pain*, and no less than 7 of these involved the lesser curvature; in all of them there was very extensive induration around the ulcer, and adhesions to the left lobe of the liver or to the anterior abdominal wall, and in 4 of them there was an hour-glass contraction. In 1 case in which the ulcer was located in the duodenum the pain occurred in definite seizures at intervals of about five days; these seizures closely resembled biliary colic, and necessitated the patient being put to bed with hot bottles and the exhibition of opiates.

Seat of the Pain.—The pain is almost invariably referred to the vicinity of the middle line, and frequently passes through to the back between the shoulders. It may be stated generally that in ulcer of the lesser curvature the pain is to the left of the xiphoid or below the left costal margin; in ulcer at or near the pyloric ring the pain is in the middle line; in ulcer of the duodenum the pain is to the right of the xiphoid or below or over the right costal margin. One cannot rely upon any particular case conforming to these general rules. I have observed patients with left-sided pain and found at the operation that the ulcer was situated in the duodenum, and conversely I have seen patients with right-sided pain and yet operation disclosed an ulcer in the vicinity of the pyloric ring.

Relation of Pain to the Taking of Food.—In 10 cases pain was relieved by the taking of food. In some cases this amounted to the well-known hunger-pain; in 6 of the 10 cases the ulcer was situated in the duodenum. Pain following the taking of food was complained of in 4 cases in which the ulcer was situated in the lesser curvature, and in these the pain occurred from half an hour to an hour after food; in 11 cases in which the ulcer affected the pyloric ring and antrum the pain occurred from one to two hours after the taking of food, and in 9 cases in which the ulcer was situated in the duodenum the pain occurred later than two hours after food, and in 1 case four hours after food. In the case of multiple ulcers the pain sequence is apt to be confusing. In the hour-glass cases the pain corresponds to that of an ulcer of the lesser curvature; it comes on soon after food, is apt to be constant, and is referred to the left side. Several patients, and more particularly those who were the subject of duodenal ulcer, were quite decided in saying that the nature of the diet had no influence on their symptoms. One intelligent man, for example, affirmed that he suffered just as much when he was on a restricted diet as when he took lobster salad and other supposed indigestible foods. In gastric ulcer, on the other hand, the nature of the diet has a considerable influence on the amount of suffering, and the majority volunteered that their symptoms were aggravated when this included butcher meat and potatoes. In cases of pyloric obstruction with butyric and lactic acid fermentation the diet naturally makes a great difference. It was quite the exception to be able to bring out any relationship between the attitude of the patient and the pain, such as would help in locating the ulcer. I should not diagnose an ulcer to be seated in the posterior wall because the patient obtained relief from lying on his face. The site of the ulcer is not to be inferred from any one symptom, but from all the features of the case. The onset of pain in the evening or during the night was a striking feature in at least 7 cases (14 per cent.). In 1 of these the ulcer was in the lesser curvature, in 4 at or near the pylorus, and in 3 in the duodenum. The night pain in the duodenal cases is a variety of hunger-pain: in the pyloric cases it was usually associated with stenosis and distension of the stomach and the accumulation and decomposition of the food taken during the day. If the patient vomited, either spontaneously or by putting his fingers down the throat, the pain was relieved and the patient was able to go to sleep again.

Tenderness in the epigastrium or over the lower ribs was observed in 16 cases (32 per cent.), and in the majority of these the ulcer was situated near the pylorus or lesser curvature. This association would appear to depend on the greater frequency with which gastric ulcer, in contrast to duodenal ulcer, leads to the formation of adhesions between the area of the ulcer and the parietal

* Read at a meeting of the Medico-Chirurgical Society of Edinburgh, March 3rd, 1909.

peritoneum. In the whole series of duodenal ulcers there were only two in which there was marked tenderness, and in both there were extensive adhesions to the under surface of the liver and to the parietal peritoneum. Along with the tenderness there is often rigidity of the corresponding rectus muscle.

The Causation of the Pain in Chronic Ulcer.

The pain of gastric or duodenal ulcer is usually ascribed to the contact of the acid contents of the stomach with the raw surface of the ulcer. I believe that hyperacidity is one of the essential factors in the production of an ulcer, but I do not believe it is the cause of the pain. When food is swallowed gastric juice is secreted at once, and therefore in an ulcer situated at the lesser curvature this should be at once exposed to its action, and pain ought to follow immediately. It is the interval which is difficult to account for. I believe that the pain is due to the movements of that part of the stomach in which the ulcer is situated—that is to say, the pain is due to peristalsis and not to contact of acid with the raw surface. We know that the exaggerated peristalsis which is visible through the abdominal wall is always associated with pain, and there can be no doubt of the influence of the taking of food in the production of peristaltic movements.

If pain were the result of contact with the acid contents of the stomach, one would expect that the recent acute ulcer with a raw surface and little infiltration of its base and margins would react most; so far as I can learn, this ulcer is usually insensitive. The ulcer which causes the greatest amount of pain is the chronic ulcer with widespread callous infiltration and peritoneal adhesions, precisely the type of lesion that would most interfere with the peristaltic movements of the organ.

In four of my cases the test-meal showed the complete absence of free hydrochloric acid, and yet in all of these pain was a prominent feature, another proof that the pain of ulcer is due to the movements of the viscus and not to the acidity of its contents.

The violent crises of pain which occur at irregular intervals in some cases of duodenal ulcer cannot be related to contact with acid contents; they are much more likely to be due to cramp-like contractions of the wall of the duodenum.

The explanation of the hunger-pain of duodenal ulcer more difficult. It is usually accepted that the pain of fasting is relieved by the taking of food, because this is followed by the shutting of the pylorus and the arrest of the passage of acid material into the duodenum. This has always appeared to me a fanciful explanation. It presupposes that during fasting acid material is passed into the first portion of the duodenum, which is obviously not the case. Is it not rather that as the stomach empties the pylorus tends to move towards or even to the left of the middle line, thus putting traction on the duodenum, and when it is the seat of an ulcer, there is pain, or at any rate a feeling of discomfort, which is relieved by the ingestion of food? Similarly, when a stomach with an anterior ulcer and with adhesions to the parietal peritoneum becomes distended, whether from accumulation of food or of products of decomposition, pain or extreme discomfort is brought about, because the stomach is displaced downwards and to the right; thus traction is made upon the indurated portion and upon any adhesions which may be present.

Vomiting.

This was present in 42 cases (84 per cent.), and therefore, next to pain, is the most constant symptom of ulcer. In 4 it was occasional; in the great majority it was a prominent feature. It is more constant in gastric than in duodenal ulcer, and attains its acme in ulcer at the pylorus with narrowing of the outlet. In these it is usually cumulative, the patient vomiting at night what has been ingested during the day. It is important to bear in mind that vomiting may be absent; in the present series there were six patients with uncomplicated duodenal ulcer who never vomited. It is more noteworthy that vomiting was absent in two cases of ulcer of the lesser curvature; in one of these there was a large, saddle-shaped ulcer with marked hour-glass contraction.

Haemorrhage.

In 29 cases (58 per cent.) there was haematemesis, and in 11 of these there was also haemorrhage from the bowel.

In 15 cases the patient vomited pure blood, and in 13 coffee grounds; 1 patient vomited blood and coffee grounds on different occasions. My records show that haemorrhage is most frequent in ulcers at or near the pylorus—13 out of 16 (81 per cent.)—while only one of these had melæna. It is next most frequent in duodenal ulcers—10 out of 17 (59 per cent.)—and it is in these that we have the highest percentage of haemorrhages from the bowel; there is therefore abundant corroboration of the current view that the combination of haematemesis and melæna is strongly suggestive of the ulcer being situated in the duodenum. Haemorrhage was less frequent in ulcers of the lesser curvature—5 out of 12—and in 2 of these there was melæna.

Test Meal.

This was carried out as a routine measure. The gastric contents showed the presence of free HCl, usually to excess, in all of the series except four. These four cases, therefore, merit special consideration; in all of them the ulcer was situated in the lesser curvature. In one case there was also an ulcer of the duodenum, and in one of them there was an hour-glass contraction of the stomach. In two of these cases the provisional diagnosis of carcinoma was made, and in the then state of our knowledge (1906) this sufficed to turn the scale in determining me to resect the affected portion of stomach, with the unfortunate sequel that one of the patients succumbed to what turned out to be a formidable operation, much more difficult than the average resection for cancer. In each of these cases microscopic examination showed the lesion to be a chronic ulcer and nothing more. In the third case the infiltration of the first part of the duodenum was so extensive that, in view of the absence of free HCl and the presence of lactic and butyric acids, one would have been inclined to regard the condition as malignant were it not that the discovery of a second area of induration in the lesser curvature presenting the typical crater of an ulcer to the fingers, turned the scale against the diagnosis of cancer, and enabled cure to be brought about by a simple gastro-enterostomy. The fourth case was one of hour-glass contraction of the stomach, and, in spite of the absence of free HCl and the presence of butyric and lactic acids, there was no doubt of the innocence of the condition, and a complete disappearance of the symptoms was obtained by anastomosing the larger proximal sac with the jejunum.

The presence of butyric and lactic acids along with free HCl is not of much significance. It is merely an indication of the stasis of the gastric contents, and does not support in any way the diagnosis of cancer. This combination was noticed in 2 cases of pyloric ulcer, in 1 hour-glass stomach with saddle ulcer of the lesser curvature, and in 4 cases of ulcer of the duodenum.

Constipation.

This is almost universal throughout the series; there are only three in which the notes record that the bowels moved every day without medicine. It was naturally much more marked in the cases with pyloric stenosis, but it occurs with sufficient frequency apart from any obstruction of the lumen to warrant the inference that the mere presence of an ulcer in the stomach or duodenum interferes with the onward propulsion of the ingesta.

Visible Peristalsis.

This was only observed in 5 cases—4 of pyloric ulcer and 1 of the duodenum. It affords a reliable guide to the degree of mechanical narrowing of the lumen brought about by the ulcer, and is to be regarded as a favourable indication from the operative point of view, as the hypertrophy of the muscular coat of the stomach with which it is associated enables the patient to derive the maximum advantage from a gastro-enterostomy.

The condition of the stomach as revealed by physical examination, distension with air, and other methods, was of service in affording information as to the shape, size, and position of the stomach, but it was only of indirect service in establishing the existence of ulcer, or its position when diagnosed.

The Diagnosis of Chronic Ulcer of the Stomach and Duodenum.

Enough has been said under the heads of the individual symptoms and signs to make it evident that in the great

majority of cases the diagnosis can be made with a reasonable approach to accuracy. There will always remain, however, a minority—and this will probably increase as patients apply for treatment at an earlier stage of the malady—in which the clinical diagnosis will be attended with uncertainty.

A *gastric neurosis*, or a gastric form of neurasthenia, which is met with in both sexes, but especially in women, is one of the affections most likely to be mistaken for chronic ulcer. The difficulty is more likely to occur in the exceptional cases, to which reference has already been made, in which there is no history of vomiting, and in which the pain is both indefinite in character and in location. This, which may be termed the latent duodenal ulcer, is particularly difficult to diagnose, and the records show that several of the cases in which I have operated and found a duodenal ulcer had been previously under treatment for neurasthenia. The risk of confusing duodenal ulcer with an affection of the gall bladder is well known, but the difficulty is usually cleared up under observation, especially by any one who is experienced in both maladies; and, in any case, in either affection a recourse to laparotomy would not be out of place.

Carcinoma of the stomach is not only liable to be mistaken for ulcer clinically, especially ulcer cases in which the test meal reveals the absence of free HCl, but also when the abdomen has been opened and the parts inspected. On looking back I think one is justified in saying that carcinoma, when present, is unmistakable. On the other hand, one is often inclined to look upon ulcer cases as malignant. One is helped in these doubtful cases when there are two apparent tumours, for these are much more likely to be ulcers than cancer. One is also helped if the duodenum is implicated in the tumour, as in gastric carcinoma this is very exceptional.

Carcinoma in the vicinity of the stomach—for example, one in the head of the pancreas—may project forwards and involve the duodenum or pylorus in such a way as to give the impression of a primary growth in one or other of these situations, and as there may be an absence of free HCl in these cases, the correct interpretation of the conditions found at the operation may be very difficult.

The Hour-glass Cases.

In my experience, hour-glass contraction is the most elusive of all the manifestations of gastric ulcer. The four examples in the present series of cases were met with in middle-aged women (38 to 49 years), who had over a period ranging from twelve months to twenty years presented the clinical features of an ulcer situated in the lesser curvature. The hour-glass constriction was only once diagnosed before operation. In this case there was peristalsis of the wall of the pyloric pouch, and the circumscribed, dome-shaped swelling thus formed was obviously too small to correspond to the whole stomach. In the second example an hour-glass contraction was considered and negatived because none of the recognized tests could be elicited; at the operation it was found that the isthmus had been drawn up behind the ensiform cartilage, and that the pyloric chamber did not even attain the size of a golf-ball. In the third and fourth examples the condition was not suspected before operation, chiefly because of the misleading histories given by the patients. It is noteworthy that one of them, a woman aged 49, had had attacks of colic-like pain in the upper and left region of the abdomen for a period of twelve months, and had never once vomited; and yet at the operation the pyloric chamber was found to be fused with the liver, the pancreas, and anterior abdominal wall, and the lesser curvature was the seat of a saddle-shaped ulcer.

Treatment of Chronic Gastric and Duodenal Ulcer.

Whatever difference of opinion may exist with regard to the treatment of the recent or acute ulcer, I expect we shall be unanimous in the opinion that the chronic ulcer can only be cured by surgical means. The histories of our cases furnish the basis for this opinion. Time, the important factor in so many cures, is apparently powerless in a chronic ulcer, judging by the periods of fifteen, twenty, and even thirty years some of the patients have suffered before they come to operation.

Restricted diet and, lavage, relieve the prominent symptoms for a time and give the ulcer a chance of

healing, which, however, it is apparently rarely, if ever, able to take advantage of. Many of our cases have been dieted and washed out for many years, and the ulcer, when seen at operation, appears as firmly established as ever.

Our reasons for recommending operation are, shortly, as follows: Because the ulcer will not get well otherwise; because the ulcer and its complications are the cause of considerable suffering, and prevent the patient from earning a living; and because the ulcer may become dangerous to life through starvation, hæmorrhage, perforation, or transformation into cancer.

The choice of operation lies between resection and gastro-enterostomy. The sphere of resection is very limited; it is often impossible—as, for example, in the diffuse ulcers of the duodenum. It is nearly always difficult, and is by no means free from danger. The resection may bring about narrowing of the lumen, and necessitate a gastro-enterostomy in addition; and, finally, as pointed out by Mayo, it does not get rid of the hyperacidity of the stomach contents, which is an essential factor in the production of the disease, so that, unless a gastro-enterostomy is added, there is the risk of the formation of a fresh ulcer in the future. The claim of those who advocate resection as the routine measure where feasible—Rydygier being one of the best known of them—is that if the ulcer is allowed to remain the risk of its becoming cancerous is considerable. So far as my own experience is concerned, this undesirable sequel has only happened once in 47 cases subjected to gastro-enterostomy. Gastro-enterostomy was performed on September 6th, 1904, for a chronic ulcer near the pylorus. When seen sixteen months later the patient was going downhill; free HCl had disappeared from the gastric contents, and an exploratory operation revealed cancer both in the stomach and in the liver. Personally I should not be influenced by the unfortunate sequel in this case to extend the sphere of resection, and that for the reasons already stated.

RESULTS OF OPERATION IN 50 CONSECUTIVE CASES OF CHRONIC ULCER.

Resections of Stomach.

Three cases with one operation death. Of the survivors, one is perfectly well three and a quarter years later; the remaining one is well two and a third years later, but has occasional pain and flatulence.

Gastro-enterostomies.

Forty-seven cases with three operation deaths = a mortality of 6; per cent. The deaths occurred in the early members of the series, before the technique of the operation was established. Two were due to a bad form of vicious circle and one to septic peritonitis.

Of those who survived the operation, 1, a tramp, was lost sight of; 5 died at various periods—1 of exophthalmic goitre, 1 of cancer of the stomach, already referred to, 1 of urinary sepsis associated with enlarged prostate, and 2 of what was reported by their doctors as acute enteritis. It is just possible that this may have been perforation of a peptic ulcer of the jejunum.

The remaining 38 are all under observation, and I am very greatly indebted to their doctors for the reports with which they have been good enough to furnish me on the subsequent history of these patients and their present condition. With a few exceptions to be mentioned presently, they all described in enthusiastic terms the benefits derived from the operation; there is an increase of weight, and in individual cases this amounted to 2, 3, and even 4 st.; there is complete freedom from the pre-existing gastric symptoms, a healthy appetite, a capacity of eating and enjoying everything, and, finally, a regular action of the bowels without medicines. There was no discoverable difference in the results, whether the operation had been performed for ulcer of the lesser curvature, for ulcer at or near the pylorus, or for ulcer in the duodenum. Even cases with extensive adhesions and the 4 cases of hour-glass stomach all fall to be included in this group of ideal results. Three of the women have since borne children; there was only a moderate amount of sickness during the later months of pregnancy. One of the male patients passed easily through an attack of typhoid fever.

In a proportion of the cases the gastric functions have been subsequently tested, in some cases years after the

operation. In those in which the stomach was previously dilated it was found to have returned to the normal, or nearly the normal size. If the stomach tube was passed from one to three hours after a meal, the food contents were found to be still present in the stomach, showing that the gastro-enterostomy opening behaves in the same way as the normal pylorus. The contents were usually found to be neutral in reaction, and showed traces of bile constituents, usually bile salts. If the tube is passed in the fasting condition, a small amount of bile-stained mucus is usually evacuated.

The exceptions to the above ideal results are comparatively unimportant; one, for example, has a ventral hernia, one is still a little anaemic, one has fullness after meals, one suffers from flatulence and occasional attacks of bile (the earliest operation case in the series), and one has a feeling of distension, and his gastric contents after a test meal show butyric acid and the absence of free HCl.

I beg to record my sincere indebtedness to my medical colleagues on the staff of the infirmary, and particularly to Dr. Francis Boyd, for their invaluable co-operation in the clinical examination of the cases here recorded.

PRIMARY DIFFUSE PNEUMOCOCCIC PERITONITIS: TREATMENT BY DRAINAGE AND PNEUMOCOCCIC VACCINE: RECOVERY.

By H. BETHAM ROBINSON, M.S.LOND., F.R.C.S.,

SURGEON TO ST. THOMAS'S HOSPITAL; CONSULTING SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN, ETC.

Not many years ago pneumococcic peritonitis was an unrecognized disease, but of later years the attention of the profession has been drawn to its occurrence through the writings of Jensen, von Brunn, and others on the Continent, and by the paper of Annand and Bowen in particular in this country.

The comparatively limited number of cases so far recorded, and the uncertain recognition of the disease, call for the publication of any further experience. I therefore offer the following contribution, which was a case of diffuse and primary pneumococcic peritonitis with an acute onset simulating perforation of the appendix.

Dorothy W., aged 9, was admitted into the hospital on the evening of April 22nd, 1938, under the care of my colleague, Dr. Sharkey, and was transferred to me the next morning.

Personal and Family History.

The father was said to suffer from some chest trouble, and there was a history of tubercle in the mother's family.

She had always been a nervous child, subject to bilious attacks. Three years before she had had measles, and two years before influenza with symptoms very similar to those of the present illness, abdominal pain and vomiting. From the previous November to February she was kept from school on account of her eyes and headache. She had many times complained of abdominal pain, which was generally relieved by micturition; she had rather a habit of holding her water.

History of Illness.

On the day before admission she had been seemingly in perfect health. At 8.30 a.m. on the 22nd she was suddenly taken ill with free vomiting, faintness, and slight abdominal pain centred round the umbilicus; she was very thirsty and feverish. In the evening, fifteen hours after the onset, she was admitted looking ill and complaining of severe abdominal pain and vomiting. The face was very flushed, the eyes bright but not sunken, and the tongue furred generally but rather dry at the tip. The pulse was 130, regular and of small volume; temperature 103.8°, and respirations 36. The chest moved well and equally, and there were no abnormal physical signs detected in heart or lungs. Abdominal movement was restricted but not absent, especially below the umbilicus; there was definite distension, but it was everywhere resonant. Palpation proved an almost universal tenderness, more marked round the umbilicus and in the right lower quadrant; here there was some increased resistance, but no distinct lump could be felt. There was no alteration in the position or size of the liver; the spleen and kidneys seemed normal, and the urine was unaltered except for an increase of urates. Per rectum there was a boggy feeling, especially on the right side, as if there was something in Douglas's pouch.

I was asked to see the child at 11 next morning, her pulse then being 150 and temperature 103.4°. The abdomen moved fairly well on respiration except on the right side below; here and across the bladder region she was tender. There was a

little rigidity over the right rectus both below and above the umbilicus. An immediate operation was decided on, as her condition suggested a perforative peritonitis dependent probably on a gangrenous appendix.

Operation.

A vertical incision was made over the right rectus below the umbilicus, opening the sheath and displacing the muscle inwards. On opening the peritoneum a greenish-yellow fluid escaped, of gummy consistency, with a few flakes of dirty-white lymph in it. Although this was generally diffused through the cavity, and the intestines and omentum were smeared over with it, yet they did not otherwise appear to be in any way altered from the normal; the appendix was absolutely healthy. A good deal of fluid had collected in the pelvis and in the right kidney pouch. There was no sign anywhere of glueing together of the intestinal coils by early adhesions. The right Fallopian tube was very definitely injected. (Subsequent inquiry elicited no evidence, past or present, of any vulval or vaginal discharge.) The glands along the iliac vessels and at the bifurcation of the aorta appeared to be a little enlarged. The peritoneal fluid was quite odourless. Drains with wicks were placed down into the pelvis and up into the kidney pouch, and the main part of the wound was closed in layers. She stood the operation very well, and was put back to bed in the Fowler position, and given $\frac{1}{2}$ grain of morphine. Saline was ordered per rectum.

After-History.

After the operation there was a gentle drop in the temperature to 99° at 8 o'clock the next morning, with a corresponding marked reduction in the pulse-rate. She was feeling much more comfortable, and there had been very little pain and no vomiting. She was given milk and water frequently in small quantities. On April 25th her condition was very satisfactory, but both pulse and temperature had again risen a little. As her bowels had not acted, she was put on magnesium sulphate in the evening. The next morning there was a very slight result after an enema. The wicks were removed from the tubes, and a considerable discharge of turbid fluid came away. Calomel, 2 grains, given at night, followed by magnesium sulphate in the morning; this resulted in four actions during the day. On this day (April 27th) the temperature again began to go up, and, as the clinical report showed that the peritoneal effusion was a pure culture of the pneumococcus, it was decided to use pneumococcic vaccine (see chart). Beyond the variations in pulse and temperature there is now not much to report except her steady progress. On May 5th both drainage tubes were removed and gauze drains substituted. On the 6th, as on removing the gauze a fair amount of pus could be pressed up from the lower abdomen, Bier's cupping for ten minutes was started; this soon produced a marked diminution in the amount of discharge. This, however, did not cease altogether, and apparently came up from the loin, so on May 27th a counter-opening was made here and a piece of gauze pulled through from front to back. This soon had a marked effect both on the discharge and the temperature. On June 6th the front wounds were healed, and on the 10th the drain was left out behind. By this date her temperature had been normal for a week, and she was beginning to get up. She was able to leave the hospital on June 15th.

She was readmitted in capital health on October 19th to have a small ventral hernia through the drainage hole dealt with. Some adherent omentum was set free, the peritoneal bulging cut out, and the freshened fascia brought together in layers. She went out on November 5th with a sound scar.

The clinical types of this disease vary as to whether the peritoneal effusion becomes localized or is diffuse. The localized form starts with acute symptoms, and tends to become chronic; at the same time there is walling-in of the effusion, which usually occurs in the lower abdomen in the region of the umbilicus. This is the type of case which in the past was probably considered to be a tuberculous abscess, and, pointing at the umbilicus, ultimately burst or was intentionally opened, with in many instances recovery.

In the diffuse form the symptoms are more markedly acute and remain so, and the signs those of a generalized peritonitis. Jensen and others have commented on the similarity of the onset to acute perforative peritonitis dependent on the appendix, and this case is another example of such.

These clinical forms of peritoneal involvement are found again, whether the peritoneum is primarily or secondarily affected. In a large number it is secondarily implicated, the primary lesion being most often a pneumonia, or a throat or ear lesion, or a pneumococcal abscess elsewhere; the blood infection from these foci is responsible for the subsequent peritonitis.

In the primary cases of peritonitis the possible origin may be traced in a few cases to an appendicitis or to an enteritis, the initial intestinal symptoms, especially diarrhoea, supporting the latter; neither of these causes appeared to be responsible in this case. As stated before, there was in this patient very great congestion

of the right Fallopian tube, in marked contrast to the surrounding peritoneum. It has been thought that the infection may ascend from below, but here there had never been observed, nor was there present, any vulvo-vaginal discharge. A point that has been urged in favour of this possibility of origin is the curiously undue proportion of cases in females, but this excess is regarded by most as only accidental. The most accepted explanation, however, is that, as in the former group, the infection comes from the blood, and this is infected by absorption from a mucous surface without any discoverable lesion. No further pneumococcal lesion was found in this case, nor was the blood examined for organisms.

The symptoms of onset agreed with those described by previous observers. In a child of apparent good health there was a history of sudden severe abdominal pain, free vomiting, but no diarrhoea, with rapid development of peritoneal signs. The localizing of the pain, first about the umbilicus and then in the right lower quadrant with the most marked tenderness and some rigidity in the same region, seemed to point to the appendix as the probable source of the trouble; in fact, it is difficult to see how one could exclude this view, bearing in mind the many cases seen of a severe first attack and where there had been previously no warning that the appendix was not healthy. In this child there was some previous history of abdominal pain and vomiting, suggesting appendix trouble.

The character of the peritoneal fluid at the operation was quite distinctive; it was odourless and of a yellowish-green colour, of gummy consistency, and with a limited number of greyish-white flakes of fibrinous coagula in it. The fluid was very little turbid, and this is explained by the early period at which the operation was performed; it later became typically purulent, but remained odourless throughout.

The treatment employed was by incision and drainage. Whether it would have been wiser, after mopping out the fluid, to have closed the cavity, as recommended by some, must remain unanswered; there are not sufficient recorded observations to support one view or the other. It may certainly be urged that the closed cavity runs little or no risk of staphylococcal contamination from outside, which is very likely to occur, and did so in this case. If the fluid should re-collect, or circumstances should otherwise determine it, the wound could be easily opened again and then drained. In another early case I shall be disposed to adopt this line of action.

With the advice and assistance of Dr. Dudgeon, pneumococcal vaccine was employed in the treatment of the case, which was considered a favourable one for such a course. It was started on the fifth day after operation, when, after an initial reduction of pulse, temperature, and symptoms, there was a marked increase again of the pulse and temperature. The injections, eight in all, were given in increasing doses (see chart), at intervals of five or six days. The satisfactory influence of the first two is well shown in the chart; after that the pus became contami-

nated, and it was from this cause that the well-marked rises of temperature occurred, masking the effect of the vaccine. On counter-drainage in the loin the temperature rapidly subsided, and she made a speedy recovery. It must be considered, I think, that the use of vaccine contributed in a large degree to the successful issue of the case.

INCISIONS FOR OPERATIONS ON THE UPPER ABDOMINAL ORGANS.

By ALEXANDER DON, M.B., C.M., F.R.C.S., M.A.,

Surgeon to and Lecturer on Clinical Surgery in the Royal Infirmary, Dundee.

THE incisions practised for operations in the upper abdominal organs are numerous, which indicates that none of them are entirely satisfactory. Kocher's and Mayo Robson's are the most used in this country, and those described by Bevan, Kehr, and Czerny less frequently. The first three have the merit of giving very free access to the biliary apparatus, the duodenum, the pylorus, and the head of the pancreas, while similar incisions on the left side are available for gastric, splenic, and pancreatic operations. The objection to these incisions is that they cut off the nerve supply of the whole upper half of the rectus and overlying skin. A central quadrilateral area undergoes atrophy in consequence. The family doctor knows best that this is no imaginary sequel. It would be of little moment were the patients to remain invalids, but to an active man or woman the injury is serious. Hernia is not common, but the anaesthesia of the skin leads to abrasions, ulcerations, and other injuries, which are more serious from their being less painful, and therefore liable for a time to escape notice and treatment. Kehr's incision leaves a part of the rectus intact, and is in this respect an improvement on the others, but he cuts off more of the blood supply, while Czerny's merely produces another fibrous intersection in the rectus, and leaves a weak median scar.

The following incisions have no doubt been often employed by others, and there seems nothing against their universal adoption. They are anatomically correct, give ample room, and, when healed, produce a firm cicatrix. The blood and nerve supply is intact, the only vessel severed being the deep epigastric artery near its anastomosis with the internal mammary.

The first incision through the rectus is used by most surgeons for exploratory laparotomies. The skin and anterior sheath are divided a fingerbreadth to the right or left of the middle line from opposite the seventh costochondral junction to the umbilicus. The sheath is dissected off the muscle on the inner side, and the muscle freed by blunt dissection from its posterior sheath, and retracted outwards as far as possible. The posterior sheath and peritoneum are then incised as far out as

convenient, and parallel to the whole length of the skin incision. Through this opening the whole of the upper abdomen can be explored, and if operation on lateral organs is deemed advisable, the horizontal limb is then added. The best point for dividing the rectus is at its umbilical intersection, but it may be divided anywhere. This intersection is readily exposed by prolonging the vertical incision if necessary, and from the lower end of this a curved incision is made upwards and outwards to the lowest part of the costal margin. This divides skin and superficial fascia only. The muscle with the skin and anterior sheath is now raised up with the left hand, and the whole cut straight outwards through the middle of the fibrous intersection till the whole thickness of the rectus is divided. The deep epigastric, or a branch, may bleed and require securing. The posterior sheath is divided $\frac{1}{4}$ in. higher up for ease in suturing later.

In very fat subjects the ends of the skin incisions are prolonged and gradually shallowed out at their ends. This gives considerably more room, and does not weaken the cicatrix in the least. When turned up the base of this flap lies along Kocher's incision. The costal cartilages can be cut from the peritoneal side if necessary for operations on the spleen or cardiac end of the stomach. With the sandbag under the patient excellent exposure is got, and the edges of the opening are not too rigid. Only one

The thick line indicates incisions in skin; the dotted line, incisions in posterior sheath and peritoneum; the fine lines, prolongations of skin cuts for stout people; the shading shows ribs, cartilages, nerves, and muscles. (Diagrammatic.)

retractor is required, and when the liver and gall bladder are rotated upwards this, too, may be dispensed with. There is thus no danger of damage to the organs. This sickle-shaped wound is closed in layers with silk, cotton, or celluloid thread as follows: The sandbag is removed, and the vertical peritoneum together with the posterior sheath is closed first. Efficient drainage may be secured through the upper end of the lateral wound before the peritoneum and transversalis fascia are brought together. When the inner end is reached the rectus is sutured at the fibrous intersection, where the suture holds well. The anterior sheath is made to overlap a little, and the fibres of the external and internal oblique and transversalis muscles are gently approximated. The skin is closed by celluloid thread or Meckel's clips.

A more perfect cicatrix can hardly be obtained, and hernia need not be feared. Bevan speaks of the possibility of necrosis at the angle, but in my own cases the union has always been perfect. To round off the angle is more difficult, and can be done with the skin incision only. The exposure obtained need not be described, as the opening must be tried to be appreciated.

THE fifth International Congress of Medical Electricity and Radiology will be held at Barcelona from September 15th to 18th, 1910. The questions proposed for discussion are as follows: (1) The present state of electro-diagnosis; (2) measurements in radiology; (3) electricity as an anti-phlogistic agent; (4) the electrolytic introduction of medicinal ions compared with the therapeutic action of the constant current; (5) the use of the x rays in the examination of the abdominal segment.

INTESTINAL OBSTRUCTION PRODUCED BY AN ENORMOUSLY DISTENDED STOMACH.

By A. ERNEST MAYLARD, M.B., B.S.LOND.,
SURGEON TO THE VICTORIA INFIRMARY, GLASGOW.

So remarkable and exceptional were certain features in this case that it seemed to me worthy of being put on record.

I have met with instances of great gastric dilatation reaching even to the pelvis, but I have never encountered anything at all approaching the somewhat extraordinary symptoms presented in this instance, nor do I know of any precisely similar illustration in the literature of gastric disease. The patient was a man suffering from advanced carcinoma of the stomach with symptoms of apparently only three weeks' standing, and these of a nature to suggest that the trouble was in the large bowel rather than in the stomach. But before venturing upon any comment upon the case I will let his history tell its own tale.

R. S., aged 66 years, was admitted to the Victoria Infirmary on May 21st, 1908.

History.

He stated that up to two years ago he had enjoyed good health, but at this time he began to lose his appetite, was conscious of a sense of oppression and fullness in the stomach, and suffered from pyrosis. Under treatment these symptoms disappeared. He then continued to take his food as before, and remained actively engaged in his work until three weeks ago, when his bowels commenced to be very costive and he was conscious of distension and gurgling in his abdomen. As the difficulty in getting the bowels to move increased, he used enemata, and thereby effected the discharge of some "little round balls." Neither blood nor mucus was seen. He had had no crampy or acute pains in the abdomen, but merely a sense of great discomfort from extreme distension. He had also noticed internal movements, evidently peristaltic. Position seemed to have some effect on his symptoms. When he lay on his left side they were increased, but diminished when he sat up, as he was then able to belch up some gas. He had not vomited, but pyrosis had been a frequent symptom. He was conscious that he was losing flesh.

Condition on Admission.

When admitted to the infirmary he was noticed to be in a poorly-nourished condition. His face was pinched and drawn in expression. His tongue was coated with a dirty viscid fur, and the teeth were in a bad condition. His temperature was 97.6°F ., and his pulse 96. He complained of no pain, but only of an uncomfortable sense of distension. On examination of the abdomen, there was seen to be very marked bulging both in front and laterally, although it was more marked in the left iliac region. No peristalsis was observed; abdominal respiration was diminished. To percussion there was a tympanitic note in the epigastrium, becoming dull down towards the iliac regions and the flanks, and there appeared to be slight shifting with change of position. A suspicion of fluctuation seemed present in the epigastrium. By palpation, "splashing" was detected in the epigastrium, and resistance and tenderness existed in the left iliac region, where slight gurgling was also heard. The area of liver dullness was diminished. Neither the heart nor the lungs presented anything abnormal. The urine was normal. During the three hours that elapsed between his admission and the operation he did not actually vomit, but seemed to cough up a little dark fluid, and a 2-pint enema which was given returned with flatus and a few small round scybala of black colour.

Before continuing the report of the case, as told by my resident assistant, Dr. N. McNeil, which proceeds to describe the operation, I will add a few additional observations taken at the time of my visiting the patient in consultation with Dr. George Halket, under whose care he had been for a short time prior to my interview.

It was three days before the patient was admitted to the infirmary that I saw him in his own house with Dr. Halket. In his general condition he was remarkable, as, taken into consideration that he was pale and somewhat emaciated, he in no way looked like a man suffering from advanced malignant and fatal disease. His chief complaint was abdominal discomfort from inability to obtain a movement of his bowels. His abdomen was greatly distended, and all indications of normal liver dullness had disappeared. There was dullness in both flanks, but tympanicity in the epigastric region and well-marked "splashing." The patient remarked that he had once before had a similar attack, which had completely passed off, and that, although this had lasted longer than the original one, he was confident that it would likewise disappear if only his bowels could be got to move. Dr. Halket, from his previous observation of the patient, had been under the impression that he was suffering from some gastric condition. The symptoms, however, which he presented at the time of our conjoint visit were so suggestive of intestinal obstruction that the suspicion was aroused in my mind that possibly we had to do with a malignant stricture of

the sigmoid or upper rectum, and that the great distension was due to an enormously dilated colon. My advice was, therefore, to give a copious enema, to be repeated if the first attempt failed to have any satisfactory result, with the further instruction that if the symptoms were not relieved he should, without further delay, be transferred to the infirmary.

Operation.

The abdomen was opened by an incision in the left flank. The intestine was seen collapsed and pressed down by what appeared to be a large tense cyst. A second incision was then made into the abdomen in the middle line, when a bluish, thin-walled cyst, with blood vessels stretched over its surface, at once presented. It was punctured, and ink-like fluid, sour to the smell and containing whitish masses of solid matter, spouted out with considerable force. Eleven pints of this fluid were drawn off, and it was then discovered that the supposed cyst was the stomach, which rapidly contracted down, and presented the normal appearance of muscle parietes. The vessels, also, which had spread over the apparent cyst, were seen to be the normal branches proceeding from the two curvatures. On further examination a mass of scirrhus was found involving the lesser curvature and anterior surface of the stomach towards its pyloric end. Nodules were also found freely scattered throughout the mesentery and omentum. The stomach wound was stitched up and both the abdominal incisions closed.

After-history.

He was greatly relieved by the operation, and the next morning was reading the daily paper with very little concern about himself, and feeling comparatively comfortable. In the afternoon, however, the distension commenced again, and on the following day the abdomen was so swollen that the stomach tube had to be passed. By this means a quantity of fluid, similar to that removed at the operation, was withdrawn. The washing-out was then continued on the succeeding days, as much relief seemed to be afforded by it. On the evening of the fourth day he still seemed quite comfortable, but shortly before 2 a.m. on the 26th he suddenly collapsed and died.

Necropsy.

A post-mortem examination was made by Dr. John Anderson, who reported as follows upon the condition of the stomach: "The stomach is greatly dilated, and its wall remarkably thin, so that without very gentle manipulation it is easily torn. The cavity contains a quantity of dark grumous fluid. A malignant stricture exists at the pylorus, of the concentric type; it extends along the anterior wall and lesser curvature for about 2 in., causing the wall itself to be about three-quarters of an inch in thickness. An area of ulceration exists on the posterior surface of the growth. The tumour tissue is more evident on the anterior wall; the lumen of the pyloric aperture is still of fair size, admitting the passage of the finger." The liver contained no secondary nodules, and there was nothing of note in the other organs or tissues.

Perhaps the feature of most striking interest among the many perplexing problems which the case presented was the extreme paucity of symptoms, and their apparent want of gravity when considered in relation to the serious nature and extent of the disease. There was one very prominent fact, however, about the patient that served to mask what otherwise might have been much more in evidence and suggestive, and that was his possession of a remarkably buoyant nervous system. He made light of such symptoms as he had, and doubtlessly disregarded others that might have proved diagnostically useful. He never once took a gloomy view of his case, and always regarded his illness as merely transitory. As stated, he was reading the newspaper the morning after the operation, and was often making jokes with the nurses and the resident assistant. Attention is specially drawn to this particular aspect of his case, because, as already stated, it admits of the reasonable assumption that he probably belittled many of the early symptoms which, in a patient of a less optimistic and cheerful nature, might have shown that an organic complaint of the stomach had been in existence for some time. Irrespective, however, of the influence of the nervous system, it is a well-known fact that carcinoma of the stomach may reach a very advanced stage without giving rise to any marked symptoms, so long, apparently, as it is limited to the body of the viscus and does not involve the pyloric aperture. In this case, as ascertained at the post-mortem examination, the finger could be passed through the pylorus; and although the disease distinctly involved the pyloric region, the canal itself does not seem to have been markedly obstructed by it. It is, however, impossible to conceive that at the time of the great distension the contents of the stomach were able to pass into the duodenum. Probably the pylorus got kinked or displaced in such a way as to cause occlusion.

The absence of vomiting was somewhat remarkable, and must, I think, be explained on the ground that the hyper-distension had completely paralysed the gastric parietes. It had become little more than a flaccid sac with walls so thin that they must have very nearly reached the bursting point. As shown at the post-mortem examination, the greatest care was required not to tear the walls in the process of handling.

Believing the case to be one probably of obstruction in the large bowel, I opened in the left iliac region, deeming it likely that such enormous distension of the colon would hardly take place unless the obstruction was seated low down in the large intestine. It was with a sense of considerable surprise that I found the bowel collapsed, and apparently so as the result of the pressure of a very tense cyst. As the report of the case goes on to relate, I then opened the abdomen in the middle line, and my remark was, when seeing this uniform tense cyst, that had the patient been a female and not a male, I should have thought that I had an ovarian cyst to deal with. The true nature of the swelling, however, at once became evident on letting out the fluid, for the sour smell and the coagulated lumps of what were evidently the result of ingested milk revealed the fact that it was the stomach which had been opened. This became still more conclusive as the muscle parietes of the viscus contracted, and the vessels, which were so stretched over its surface, were seen to be the normal branches extending over the anterior surface of the organ from the greater and lesser curvatures. As gastric obstructive symptoms had never apparently been a feature in the history of the case, I thought it quite possible that, having relieved the great distension, the pyloric aperture might become sufficiently permeable. I did not, therefore, perform gastro-jejunostomy; and, still further, the marked evidence of widespread malignant disease did not render such a proceeding worth undertaking in view of the above possible competency of the pyloric passage. The nature of the fluid was somewhat striking. In appearance it was more like ink; but in constitution it was probably gastric secretion mixed with blood. From the large quantity removed at the operation—11 pints—and subsequently, it hardly seemed possible to believe that it consisted solely of altered blood, but that the major part of the fluid must have consisted of an excessive gastric secretion, for at no period did the patient seem to be suffering from any great loss of blood.

In reviewing the treatment of the case by that superior wisdom which is always derivable after the event, to have simply passed the stomach tube would probably as effectually afforded relief as did the direct incision into the stomach, for it was the method adopted during the four days that life lasted, and which always gave him comfort. But such treatment would have thrown but little light on the true nature of the disease, although it would certainly have aroused suspicions regarding its possible location in the stomach. An exploratory operation would, therefore, doubtlessly have been executed, supposing the patient's condition had been such as to admit of its execution being advisable. Death was evidently due to sudden cardiac failure, a result not unlikely either of the naturally enfeebled condition which, in spite of the patient's buoyant nervous system, was evident; or of possibly some interference with the action of the heart as the result of great gastric distension.

A REPORT on the malarial investigations in Mauritius from November, 1907, to February, 1908, by Major C. E. P. Fowler, R.A.M.C., who was associated with Major Ross in the recent work conducted in that island, has been issued. It contains details of the outbreak of malaria in 1866. This outbreak in an island supposed to be non-malarial forms one of the most interesting epidemiological facts in the whole history of malaria. The report contains recommendations as to prevention, and a permanent staff for antimalarial work has been already partly formed. It will not undertake major works, its duty being minor works and the keeping in order of the major works after completion. A series of most excellent photographs with which the report is illustrated indicate very clearly the tropical nature of the vegetation and the general type of scenery, which resembles that of the West Indian islands very closely. Leaving out of account altogether major works, the minor works will necessarily prove very expensive in such a place, but if the health of the island is to be improved they will have to be carried out.

REPORT CXII.

OBSERVATIONS ON THE PHYSIOLOGY OF THE FEMALE GENITAL ORGANS.

BY
W. BLAIR BELL, and PANTLAND HICK,
M.D., B.S. LOND., M.B., B.S. LOND.,
ASSISTANT GYNAECOLOGICAL MEDICAL REGISTRAR,
SURGEON, ROYAL INFIRMARY, ROYAL INFIRMARY,
LIVERPOOL. LIVERPOOL.

III.—THE CORRELATION OF THE UTERUS AND OVARIES.

In this paper we shall give the results (for the most part histological) of several series of experiments which bear upon the correlation of the ovaries and uterus, apart from the metabolic relations existing between these organs in regard to menstruation, which have already been discussed.

The experiments performed consisted of :

- A.—1. Removal of ovaries and subsequent histological examination of the uterus.
2. Removal of ovaries during pregnancy.
- B.—Removal of uterus and subsequent examination of the ovaries.
- C.—Ligation of uterine cornua :
 1. Without removal of ovaries.
 2. Synchronous with removal of ovaries.
 3. Subsequent to removal of ovaries.

The animals operated upon were for the most part rabbits. Three bitches were also used.

Most of the above experiments have been carried out by Bond, Marshall and other observers, but, inasmuch as there have been to some extent conflicting statements made in respect to the results obtained, we have been tempted to carry out these experiments ourselves in order that we might make up our own minds on several of the contentious matters, and on those points concerning which, on

questions of the greatest importance, such as the effect of the removal of the uterus upon the ovaries, will only be settled by prolonged experiments upon monkeys, or by clinical observation on the human subject ; but of this we shall have more to say later. The fact, however, remains that the adult rabbit's ovary is of a very different histological structure from the dog's ovary or the human ovary. It has, however, been a matter of surprise to us that we have not come across adequate appreciation by those who have used rabbits in their experiments of the great difference between the histological structure of these ovaries and that of the human ovary. This difference only becomes marked in the adult rabbit, and may be summarized by the statement that in every normal rabbit—whether virgin or multiparous—the ovary is mainly composed of large cells, sometimes hardly to be differentiated from those which fill the corpora lutea, while there is practically no ordinary stroma. The ova themselves do not appear to be numerous, and are situated near the periphery. (See Fig. 1.) The adult rabbit's ovary, in fact, appears to be of an extremely glandular nature (see also Fig. 2), and in this respect entirely different from the dog's and the human ovary. (See Figs. 3 and 4 respectively.)

These large glandular "stroma" correspond, of course, with the "interstitial" cells which have been investigated by Miss Lane-Claypon.¹ In her opinion, based on careful histological work, these cells are derived from the germinal epithelium, as also are the ova and follicular cells. We have not conducted any detailed research into their origin, but it seems to us that this method of origin is a little strange, seeing that in the ovary of the young rabbit these interstitial cells are entirely absent or very few in number, while primordial ova seem to be more plentiful than in the adult (see Fig. 5).

Whatever their origin, there is no doubt that the presence of the interstitial cells makes the ovary a more glandular organ in the rabbit than in the human subject—the very friability of the adult rabbit's ovary being of itself evidence of a considerable difference of structure from that obtaining in most other mammals. Fraenkel² has recently made a long and important contribution on the subject of *la glande interstitielle de l'ovaire*, as it was originally called by Limon. After examining 45 species of mammals he concluded that these cells vary in extent in all, but are most marked

Fig. 1.—Adult rabbit's ovary. $\times 200$.

Fig. 2.—Adult rabbit's ovary showing interstitial (glandular) cells. $\times 600$.

theoretical and clinical grounds, we have held views contrary to the results generally obtained. We may say briefly that for the most part our results correspond with those obtained by other observers, but we have been forced to the conclusion that the rabbit is not the best animal on which to carry out experiments, the results of which are estimated by histological examinations of the ovaries, if we wish to compare these results with conditions obtaining in the human subject. Indeed, we believe that certain

in rodents. (We have found them constant in rabbits.) In his (Fraenkel's) experience he has found no trace of this glandular formation in the human subject. In view of these investigations by Fraenkel, and by ourselves in a very small way, we would suggest that the variation may be in proportion to the activity of the thyroid gland, which is notably inactive in rabbits.

Attention has already been called to the close relationship which exists between the ovaries and the thyroid

gland in regard to the menstrual function and to the calcium metabolism (see Papers I and II).

RESULTS OF EXPERIMENTS. SERIES A.

I.—Effect of Oophorectomy upon the Uterus.

In this experiment we wished to discover, if possible,

(d) Doe, full grown. Oophorectomy. Animal killed and uterus examined three and a half months later. The condition alluded to is seen in this case most clearly (see Fig. 10). The endometrium is quite thick, while the muscular layer is represented by a very narrow band. This animal was pregnant when the ovaries were removed.

It may be of interest to mention here the case of a patient, aged 35, from whom the uterus was removed by

FIG. 5.—Bitch's ovary. $\times 200$.

FIG. 5.—Ovary from rabbit a few weeks old. $\times 200$.

whether the atrophy which is known to occur in the uterus after removal of the ovaries affects more the endometrium or the muscular layer. For the experiment we used one bitch and rabbits. The following are illustrative of the results obtained:

(a) Sable mongrel bitch, aged 6 weeks. Oophorectomy performed. Animal killed and uterus removed nine and a half months later. It will be seen from Fig. 6 that there is a general arrest of growth which affects the whole uterus, and further that there is some degree of atrophy—most apparent in the muscle layer—which is readily seen on comparison with the uterus from a twin sister, removed on the same day that double oophorectomy was performed on this bitch (see Fig. 7). Had the uterus, shown in Fig. 6, which was 10 months old, remained *in statu quo* after oophorectomy, it should have resembled that shown in Fig. 7. There is, therefore, arrest of growth and then atrophy, and the latter most marked in the muscle layer.

(b) Doe, aged 6 weeks. Oophorectomy. Animal killed two months later and uterus examined. A section is seen in Fig. 8. The same condition of affairs is seen in this as was evident in the last case. There is some atrophy of the endometrium, but want of development and atrophy are most apparent in the muscular layer. At one point there is an area of exceptional thinning. This is most unusual and is difficult to account for. In connexion with these two cases it may be contended that, owing to the fact that the uteri had never become active (see Paper IV), the muscle layer had in consequence not developed. This point will be further alluded to presently.

(c) Doe, full grown. Oophorectomy. Animal killed and uterus examined three months later. A section of this uterus (see Fig. 9) shows that the changes which have occurred are most marked in the muscle layer, and that the endometrium is still apparently normal. This is better seen in the section than in the photomicrograph of it.

FIG. 4.—Human ovary (adult) $\times 200$, with segment showing structure of the stroma $\times 600$.

one of us by operation (owing to extensive adhesions to the appendix, etc.). The ovaries had both been removed (by another surgeon) for dysmenorrhoea four years previously, which of course influenced us in removing the uterus. The organ removed was examined microscopically (Fig. 11). The glands exist in large numbers and stain well. The delicate stroma of the endometrium and the muscle fibres are both replaced by fibrous tissue.

It would appear, then, that when the ovaries are removed in a young animal the uterus remains in an infantile condition, and undergoes slight general atrophy, which condition may be changed into one of general fibrosis of the organ after many years.

This condition of fibrosis is shown in Fig. 12, which is a section of an infantile uterus removed from a human adult. At the same time a rudimentary uterus may coexist with functioning ovaries, although this uterus may be a mass of fibrous tissue, as is seen in Fig. 13—a section of a rudimentary uterus removed by one of us from a hernial sac. (Owing to the extreme hardness, it was impossible to obtain a good section.) In this case the ovaries were proved to be active, or at any rate to contain corpora lutea on histological examination (Fig. 14).

tain corpora lutea on histological examination (Fig. 14).

Conclusions.

1. Removal of the ovaries in young animals causes the uterus to remain infantile—atrophic changes eventually occurring.

2. Removal of the ovaries in adult animals produces first of all an atrophic change in the muscular layers; and this

in time may cause atrophy of the endometrium, probably by interfering with the circulation, the whole organ becoming invaded by fibrous tissue after sufficient lapse of time.

3. Functional ovaries may coexist with infantile uteri.

the secretion of the corpus luteum was necessary for the implantation of the ovum. There are, however, still those who assert that the operative manipulations cause the abortion which usually occurs. We are inclined to think that it is not the operative manipulation altogether, in

Fig. 12.—Infantile uterus from adult woman. × 200.

Fig. 13.—Rudimentary uterus from the hernial sac of an adult woman. × 200.

II.—Removal of Ovaries during Pregnancy.

In these experiments we endeavoured to remove the ovaries of rabbits at different stages of pregnancy as estimated from their connexion with the buck. The following are illustrative cases:

(a) Black doe. Opened in the anticipation that she was a few days pregnant. As pregnancy could not be detected, the ovaries and uterus were examined and handled and the abdomen closed. There was no further connexion with the buck. Twenty-three days later one young one was born alive. This case was therefore regarded in the light of a control experiment.

(b) Grey doe. Oophorectomy was performed on the seventh day. The uterus was enlarged and small nodules visible. No abortion was seen to occur. On the thirty-third day after operation the abdomen was opened, and the uterine cornua were found to be very small. Abortion had undoubtedly occurred.

(c) Black doe. Oophorectomy was performed on the fourteenth day of pregnancy. Abortion took place on the following day. The animal was killed twenty days later and the uterus found to be quite small.

(d) White and grey doe. Oophorectomy was performed on the twentieth day of pregnancy. Abortion occurred on the following day.

Fig. 14.—Ovary from hernial sac of an adult woman (same case as Fig. 13). × 200.

Other similar experiments were performed, with the invariable result that abortion occurred in every case in which oophorectomy was performed. Great care was taken in all cases not to expose the uterus, nor to handle it, and the operation was always completed in two or three minutes.

There has been much discussion in connexion with this question since ignipuncture was first performed upon the corpora lutea of pregnancy, and Fraenkel¹ claimed that

view of our control experiment; at the same time, we do not think that a comparison can be made between rabbits and the human subject in this respect, for there are undoubted cases on record in which the ovaries have been removed from women early in pregnancy (six weeks), and where there could be no doubt that the whole of both ovaries was removed, and yet the pregnancy continued to full time. A good example of this is the case reported by J. E. Gemmell,⁴ with the subsequent history of which he has kindly acquainted us.

It would be fair, therefore, to say that while the internal secretion of the ovary is favourable to the continuation of pregnancy (and this will be easily understood by a reference to what we have already stated in connexion with the relation between the ovary and the calcium metabolism), on the other hand, this secretion is not absolutely essential in that respect—at any rate, in the human subject. That our experiments and those of others on rabbits have given positive results may be explained by a consideration of what has already been said in this paper as to the structure of the rabbit's ovary.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE SKIN LESIONS CAUSED BY THE MILLEPORA.

Among the many forms of dermatitis caused by various animal and vegetable agencies, one of the most severe is that inflicted by the hydroids of the hydrocoralline millepores. The stony colonies of these hydrocorallines are generally called "corals" by the dwellers on coral reefs, and the Malays have given them the name of "Karang gatal," or itchy corals. In most of their obvious characters these colonies closely resemble the harmless madrepora corals, which possess no power of causing skin lesions. In the case of the millepores, the injury is inflicted by numerous thread cells, whose spent threads may be seen waving over the surface of colonies kept under observation, and the injury that they cause may be very severe.

The immediate signs of contact with a colony are acute erythema and severe pain. In cases in which the contact

area is large, papules rapidly form and become pustular, and a very extensive desquamation follows.

In the case figured, the flexor surfaces of both forearms were extensively affected. The patient was a Chinaman, who, in his efforts to avoid being knocked down by a wave, had grasped a colony of the millepore. Large pustules formed later on the sites of the stings, and the desquamation was extensive. One curious feature of the lesion is its lasting nature, for the site of a sting will remain red, and will sweat profusely, for more than a fortnight after contact with the colony. It is of interest that the different facies of the species *Millepora* possess different powers of stinging, and the sting of the facies *Alaicornis* is more severe than that of *Complanata* or *Verrucosa*.

FREDERIC WOOD JONES, B.S.Lond.

THE TREATMENT OF PROLONGED CASES.

In a hospital resembling that built by the late Sir John Jaffray at Birmingham for the purpose of relieving the congestion of a large city hospital (an institution in which the patients require active treatment, which is neither a

convalescent home nor a hospital into which patients are received first hand), the question of the means of promoting a quick return to health of those who have missed the first period of their allotted time is not easy.

A number of the cases suffer from wounds which have not healed by first intention, the cause sometimes, but not always, being an invasion of the wound by micro-organisms; others are tuberculous cases which have required surgical aid. The crux of the treatment of these prolonged cases would seem to be a constant ringing of the changes in the use of the various methods to promote healing at our disposal.

Briefly, these are change of air, change of food, constant change of local treatment, treatment by vaccines, rest. Local treatment resolves itself into renewed stimulation by free drainage, congestion, depletion, immersion. With regard to drainage, rubber tubing gives a far better result than gauze wicks, which do not seem sufficiently cleanly in the treatment of sinuses, however narrow they may have become.

I have been singularly unfortunate in that I have scarcely ever seen a good result, either in my own cases or those of others I have been privileged to watch, following congestion treatment of a part by proximal constriction with a rubber bandage. The theory and simplicity of the method must appeal to every medical practitioner; but, personally, I have never materially hastened the return to health of any patient by this method as far as I am able to judge.

Cupping, on the other hand, has yielded splendid results in the treatment of surgical wounds which have not reacted as they should to the care bestowed on them. The local congestion produced by cupping, followed no doubt by temporary vasomotor paralysis and an active flooding of the part with fresh lymph, has led to rapid recovery; especially is this true in the treatment of empyemata. Of the many lotions in use, two seem to stand out rather more than the rest—namely, *izal*, which has a favourable action on tuberculous granulation tissue and tuberculous lesions of old standing; the other a solution of chloride and citrate of sodium. The action of these two salts is well known, and, when used in combination with citric acid given by the mouth in 30-grain doses thrice daily, the time of healing of sluggish wounds and tuberculous empyemata has been reduced by at least one-third. Severe compound comminuted fractures in long bones have shown gratifying attempts at throwing off sequestra and rapid union under the influence of these methods.

The constant striving after something new in the practice of medicine brings home most forcibly the consideration that we can after all only place the patient in the best position for the patient to help himself.

C. N. SLANEY, M.R.C.S.
Birmingham. Resident Surgical Officer, the Jaffray Hospital.

A CASE OF HYDROPHOBIA.

A MAN attended suffering from what appeared to be hydrophobia, but the length of the incubation period made one pause before pronouncing a definite opinion.

Sixteen years previously he had been bitten by a mad jackal, which sprang up at him and fastened on his face. He strangled it, but its grip was so tight that only with difficulty could it be removed after death. He used native medicines and the wound healed without causing him any further trouble.

Two days before coming to us he had some slight fever, and on the morning of coming awakened at 4 a.m. with violent sickness. On admission the temperature was 101° F., with quick, irregular pulse, and he complained of not being able to eat or drink though suffering from great thirst. We tried him with a little water, and he made a great effort to swallow, but in the act he had such violent spasms that we desisted. He stayed with us all that day and night, the spasms becoming more frequent and independent of food or water. His speech, too, became more difficult and his pulse weaker, and every now and then he had a respiratory spasm. We tried to feed him by nutrient enemata, but that also caused the spasms, and he besought us not to attempt it. With great difficulty he managed to swallow two or three grains of rice rolled up into small pellets and sucked a little bit of cloth which had been previously soaked in water.

The next morning, at his own most urgent request, he was allowed to be taken home, and died that evening. From one who was with him after he left us I learned that he retained consciousness to the end, and never became violent. He had always been a strong man, leading an open-air life as a gardener, with no tendency to hysteria, and there appeared to be no other cause to which one could attribute the symptoms. The marks of the wound were visible on his face, and the history given was corroborated by others. We could get no history of any fresh inoculation during those sixteen years, and were, therefore, forced to the conclusion that this was a case of hydrophobia with an exceptional incubation period.

EAST LONDON HOSPITAL FOR CHILDREN.

DOUBLE EMPYEMA WITH PNEUMOCOCCAL INFECTION OF THE
SKIN AND CONJUNCTIVAE.

(Under the care of Dr. J. A. COUTTS.)

[Reported by D. L. MORRISON, M.D. Edin.]

G. S., a fat healthy looking boy, aged 7 years, was admitted to the East London Children's Hospital, Shadwell, on August 9th last, with a one day's history of pain on the left side of the chest below the nipple. He was rather apathetic and inclined to be drowsy. The temperature was 103°, and the pulse 136. The breathing was easy and at the rate of 40 per minute.

Immediately below the left nipple there was slight dullness, harsh breath sounds, and pleuritic friction. Two days later the dullness had extended round to the back, and faint bronchial breathing was heard at the left base.

The complexion was of a healthy red, but soon the patient became flushed. The flushing, which was a prominent feature throughout the illness, presented a mottled appearance, extending down over the chest and arms.

By August 17th the breathing had become much distressed, the patient had assumed a very bloated look, and altogether he appeared extremely ill. There was absolute dullness and oegophony at the left base, with some impairment of resonance also at the right base. On the left base being explored, thin pus containing pneumococci was obtained.

Next day a piece of rib was resected, and 6 oz. of pus evacuated.

On August 23rd the wound was discharging freely, but the breathing was still very distressed. The temperature still kept up, the pulse-rate was 144, and the respirations 56.

On August 27th, as the dullness at the right base had increased, it was explored, and thin pus containing pneumococci found. Under cocaine, by simple intercostal incision, about 6 oz. of pus were then evacuated.

On August 30th both wounds were discharging freely. Around the one on the right side the skin had become

harsh and dry, and whitish blebs had made their appearance. There was also conjunctivitis of the left eye.

On the next and following days the whole surface of the skin of the face, arms, legs, and back became very harsh and dry. The blebs, which began round the wound on the right side, rapidly spread up the back on to the right shoulder, and on September 1st they had reached the right side of the neck and face. The blebs, which varied much in size, were of a white colour, and in about forty-eight hours after appearance burst, and the epithelium then peeled off. Their contents yielded a pure culture of the pneumococcus, as did the discharge from the conjunctivitis, which now affected both eyes.

On September 4th the patient began to improve; the discharge from the empyema wounds became less, and the skin of the back, face, and neck desquamated in large flakes.

From this date onwards the improvement continued. The discharge from the wounds became daily less, and on September 18th both wounds were quite healed. The epithelium of the entire body, including that of the scalp, desquamated, at first in large flakes, and later in small particles. The desquamation continued for quite three weeks after the appearance of the blebs.

On September 24th the boy was discharged to the convalescent home at Bognor.

This case seems worthy of record from the extreme rarity of pneumococcal infection of the skin. It is also of interest in showing the advantages of treating certain empyemata by the method of simple intercostal incision as opposed to resection of a piece of rib. In this case the empyema on the left side was operated on by resection of rib nine days before the right side was opened by simple incision, yet the latter drained quite as freely, and the wound had healed up on the same date as the one operated on first.

The advantages here of treatment by simple incision were therefore great, for at a time when the patient was very critically ill it was possible to operate speedily under local anaesthesia without the slightest shock to the child, and with a more favourable result.

For permission to publish this case I am indebted to the kindness of Dr. J. A. Coutts, under whose care the patient was.

JOHN LANGTON, F.R.C.S., in the Chair.

Fracture of Base of the Skull.

MR. L. B. RAWLING, in a paper on some points in the surgical treatment of fracture of the base of the skull, said that profuse and continuous haemorrhage from the external auditory meatus suggested the probability that the surgeon had to deal with a case in which there was an extradural extravasation and an extensive fracture of the petrous bone, probably involving the tegmen. Plugging of the external auditory meatus was to be condemned, inasmuch as the free escape of blood was the one factor that prevented cerebral compression; and operative measures for the relief of the extravasation were to be seriously taken into consideration, even in the absence of all the classical symptoms of middle meningeal haemorrhage. Syringing of the ear was absolutely contraindicated, on the ground that the lacerated tympanic membrane and comminuted tegmen tympani exposed the patient to grave risk of meningeal infection. After investigating a large number of cases of fracture of the base of the skull—about 300 in all—during the past six years, he was enabled to classify the cases into three groups: (1) Where the temperature rose steadily and progressively to 103° or more, the reaction from the primary collapse stage being of a marked and forcible nature, and the patient dying with definite evidence of cerebral compression. (2) Where the temperature rose to 100° to 102°, and there "marked time." That was the "crisis" of the case, a further rise or fall almost invariably indicating death or probable recovery. (3) Where the temperature remained subnormal, the

patient remaining in a condition of severe cerebral shock and usually dying within a few hours. Venesection was a valuable means of reducing increased intracranial pressure. It was mainly of use in those cases that hovered between what one might call early or slight compression and the fully developed condition. "Decompression" operations might be carried out over the cerebellar fossa or over the temporal region of the skull. The temporal operation, more correctly known as the "intermusculo-temporal" operation of Harvey Cushing, often brought about the most satisfactory results. The advantages of the operation were the frequency with which the bony lesion occurred in the middle fossa of the skull, the fact that cerebral contusions were especially liable to involve the tip of the temporo-sphenoidal lobe, the exposure of the meningeal territory, and the ease of determining the presence of an extradural haemorrhage, the possibility of draining through a split muscle rather than directly through the scalp, the subsequent protective action of the muscle in case a hernia tended to form in consequence of traumatic oedema, and the subsequent absence of any deformity, the skin incision being carried out in the main through the hairy part of the scalp. With regard to lumbar puncture, he did not look upon that method as of any use in the treatment of injuries to the head. From a diagnostic point of view, the presence of blood in the cerebro-spinal fluid, as withdrawn by lumbar puncture, suggested the presence of intradural haemorrhage, nothing more. He had never seen the slightest benefit result from that mode of treatment.

Mr. G. TEMPLETON read a paper on a case of gastric dilatation associated with extreme cyanosis.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Friday, February 12th, 1909.

A. R. PARSONS, M.D., President, in the Chair.

Tumour of the Brain.

Dr. BEWLEY exhibited a specimen of cerebral tumour:

The patient, a railway guard, had five severe epileptiform fits at intervals between June and November, 1907. He complained of attacks of a tingling feeling in his left side, which was relieved by severe rubbing. He once in hospital had an epileptiform fit, beginning in the left arm. He never had headache throughout, nor did he ever vomit. He had no optic neuritis. Still, they could not help thinking that there must be a brain tumour on the right side of the brain, and from the frequency and pronounced nature of the attacks they thought it a cortical lesion, but the evidence as to localization was not great. Knee-jerks were absent. There was no paralysis; the man could walk very well, and was apparently in good health. He was admitted to hospital on November 14th, and went home for Christmas on December 24th. Four weeks afterwards he returned a good deal worse. There was almost complete paralysis of the left arm and incomplete paralysis of the left leg, anaesthesia of the left arm and leg, and great drowsiness. The left side of the face was slightly paralysed. The drowsiness continued and merged into coma, and he died on February 11th comatose. The brain was hardened by a method suggested by Dr. Leeper: A large aspirating needle was passed through the orbit and back into the subdural space, and through it a quantity of formalin was poured in. The brain preserved its shape exceedingly well, and the sections exhibited showed the tumour clearly.

The suspicion that it was a cortical lesion was not correct. It was an infiltrating glioma, and was interesting from the absence of the three cardinal signs of tumour and from the history of epileptiform seizures, and showed the difficulty of diagnosis in some cases of brain tumour.

Dr. LEEPER said the method to which Dr. Bewley had referred was taught to him by Professor Marie at Paris. He used it with satisfactory results in the case of insane persons who were a long time dying. He thought the epileptic seizures might have been due to multiple thrombosis. It was suggested that the blood of epileptics became more acid than normal, and that thrombi formed.

Septic Endocarditis starting from Congenital Pulmonary Narrowing.

Dr. BEWLEY related a case:

The patient was a man, aged 32, who since childhood had been told that there was something wrong with one of the valves of his heart. About July or August, 1908, he began to suffer from chills and rigors. These recurred from time to time, and about

September he got some pleuritic trouble on his left side. When in Cork he suffered from pain in his right side, and Dr. Pearson, of Cork, found some pleural trouble. He had a good deal of fever. Dr. Pearson found he had a loud systolic murmur heard all over the region of the heart, but specially loud over the second left costal cartilage. He thought he had a congenital narrowing of the pulmonary orifice. The patient was afterwards brought to Dublin and put under Dr. Bewley's care. He looked ill, and had some degree of irregular temperature. He had wasted a good deal. His liver was palpable, but seemed fairly normal in shape. A trace of albumen was present in the urine. He had a slight cough. Dr. Bewley thought the case was probably one of general tuberculosis, but no tubercle bacilli were found on examination. Another possibility was that there was a concealed focus of suppuration. The third idea was that it was a case of septic endocarditis. He did not himself think so, as there was no sign of emboli in the body. The patient became gradually weaker, and died in ten days. When the heart was removed he noticed that the two ventricles had approximately the same thickness, the muscular walls. The tricuspid orifice was slightly smaller than one would expect, and rather smaller than the mitral orifice. In the right ventricle he found a constriction about $\frac{1}{2}$ in. below the pulmonary valve. When they opened the pulmonary artery they found, starting from the constriction and growing up to the valves, which looked fairly healthy, an enormous mass of vegetations. There was also a small opening in the septum between the two ventricles. The left side of the heart and the aorta were perfectly healthy. They found scattered through the lungs a great many masses of infarcts surrounded by zones of inflammation; one or two were breaking down into little cavities.

The diagnosis was a slow form of septic endocarditis, grafted on a congenital narrowing of the right ventricle just below the pulmonary orifice.

The SECRETARY said the sections of the vegetations under the microscopes were crowded with micro organisms. There were present a diplococcus and a Gram-staining bacillus. Inoculations from a very mixed culture tube made from one of the infarcts killed two rabbits in the course of a few hours. He recovered two organisms from the animals. He was almost certain that the diplococcus was the pneumococcus, but he did not yet know what the bacillus was.

Dr. BEWLEY, in reply to Dr. KELPATRICK, the PRESIDENT, and Dr. HARVEY, said he only had charge of the case ten days, and during that time the patient was obviously dying. He could not find bacilli in the sputum, and he did not get any examination of the blood made. The condition might have been due to some roughness about the constriction and the increased force. He did not think there was any change of aeration. The pressure on both sides was probably much the same, so that there was evidently no free flow of blood between the two sides. All the other organs were healthy; he did not examine the brain. There was no trace of sepsis except in the lungs.

Duodenal Ulcer.

Dr. JAMES LITTLE exhibited a specimen:

The patient was of the age, about 60, when duodenal ulcers were in his experience, most frequently seen, and he thought that nearly all he had seen had been in men, and he had seen more in private practice than in hospital practice. The man was well nourished and healthy-looking, but for five or six months he had been subject to abdominal pain, which was in proportion to the solidity of the food he took. The pain was rather to the right of the navel. About ten days before admission to hospital he had two bleedings from the bowel, but he did not seem to think himself very ill. After three or four days in hospital he passed half a chamber vessel full of bright-coloured blood, which looked as if it had escaped from the intestine not very far up. No trouble was found, however, in the rectum or descending colon. He had a further bleeding, and later he suddenly vomited for the first time a large amount of blood. On the same evening he had another large haemorrhage, and died an hour or two afterwards. At the post-mortem examination they found a duodenal ulcer, and the cause of death was the rupture of an artery in the floor of the ulcer, which really was the head of the pancreas. He had never before seen death under the same circumstances. There was a second ulcer in the duodenum.

The PRESIDENT asked if the man had exhibited any symptoms of hunger pain.

Mr. WHEELER had had five cases recently: one was verified by post-mortem examination and four by operation. All were past middle life, but none of the age of 60. In four out of five duodenal ulcer was diagnosed chiefly on account of the hunger pain, which came on generally on the right side about four hours after food, and was relieved by eating something. Vomiting was irregular, and had no relation to food. In the fifth case the ulcer had perforated

when the abdomen was opened, and was not diagnosed; the duodenum was practically rotten and leaking.

Mr. STOKES said Mayo found that 69 per cent. of ulcers were duodenal, and in males the proportion was still higher. Gastric ulcer was rather commoner in females. The hunger pain was found in any lesion of the middle gut.

Dr. MOORHEAD said that of two cases of duodenal ulcer he had seen, one was in a woman aged 50, and typical hunger pain was present. The ulcer was found by operation, and a complete cure effected. The other case was a young man, aged 22, who never had the hunger pain. He had symptoms of perforation, and a perforated duodenal ulcer was found on operation.

Dr. CARILL said the age limit was probably the final crisis after a chronic trouble of many years, so that duodenal ulcer began much earlier than was usually thought. The hunger pain was found in several other conditions. A definite time relation could be found by giving the patient something indigestible, like pork, to delay the pain.

Dr. LITTLE, in reply, said he had no doubt that the hunger pain was clinically important, but it was certain that it was not so pathognomonic as it was supposed to be.

Tumour of Brain.

Dr. LITTLE also exhibited a specimen of cerebral tumour taken from a girl aged 17.

She had come to hospital about ten days before, having sickened and vomited on the Friday previous to the Tuesday on which she was admitted. On the Sunday she became unconscious. She was unconscious on admission, and appeared to have paralysis of both sides of the body. She had very strongly-contracted pupils, and, remembering a similar circumstance in a case many years ago, he made a diagnosis of a pons lesion. He made a *post-mortem* examination, and in the centre of the pons he found a hæmorrhage as big as a marrow-fat pea.

Professor SCOTT said it was a pure hæmorrhage, but not of an ordinary type. Nearly every artery appeared to have weakened walls, and the apparent tumour was made up of innumerable discrete hæmorrhages.

Stenosis of Tricuspid and Mitral Orifices.

Dr. COLEMAN exhibited a heart with stenosis of tricuspid and mitral orifices.

The patient was a girl about 24. She had a history of attacks of rheumatic fever. She was admitted to hospital about six months ago, and died in five months. The prominent symptoms were dyspnoea, cyanosis, and some oedema, and two or three weeks before she died she had embolism of the right femoral artery, and in the case of the brachial artery the nutrition of the limb was retained, but she got gangrene up to the knee in the right leg, and amputation was performed. He diagnosed mitral stenosis from the physical symptoms. An unusual point was that the presystolic murmur was heard over a more extensive area than usual. A thrill was present, but only over the mitral area. She was found at the *post-mortem* examination to have well-marked mitral stenosis. The mitral orifice was reduced to a mere slit, and she had considerable stenosis of the tricuspid. In addition, she had recent vegetations on the aortic cusps.

Dr. BEWLEY and Dr. LITTLE recalled similar cases.

UNITED SERVICES MEDICAL SOCIETY.

Wednesday, January 13th, 1909.

Surgeon-General Sir ALFRED KNOGH, K.C.B., D.G.A.M.S., in the Chair.

The Work of Medical Officers of the Territorial Force.

LIEUTENANT-COLONEL C. H. MELVILLE, R.A.M.C., read a paper on what can be done by medical officers of the Territorial Force in time of peace to prevent disease and promote physical efficiency in time of war. He divided this into three heads: Sanitary education, the collection of sanitary intelligence, and the encouragement of physical education. First: The necessity of educating the men composing the Territorial Army in the essentials of camp sanitation. The two great functions of sanitation—water supply and the removal of excreta—had up to the moment been performed for their benefit; the turning of a tap, or the pulling of a handle comprise all the individual effort demanded of the men in these two directions. If either the tap or the handle should fail to perform their proper duties, the plumber or the turncock were at hand to rectify matters. In camp he was individually responsible for preventing his excreta, which could no longer be removed automatically, from becoming a source of nuisance or

danger to himself or his comrades. The speaker emphasized strongly that the responsibility of the soldier with regard to his excreta and their proper disposal was absolutely and directly personal. The immediate burial of excreta was the first and leading principle of all camp sanitation. This was the first thing that the men and officers of the Territorial Army should be taught, and the burial of excreta must be done quickly. Men must also be taught moderation in drinking—not merely alcoholic drinks, but drinking generally. With reference to preventive inoculation against enteric fever, he thought that every young man who was going to be exposed to the risks of campaigning should be inoculated. As a practical measure extended to all ranks of the Territorial Army in time of peace (it would be impossible to perform the inoculation after a war had broken out) there were practical difficulties in the way. Still, of the benefits of inoculation there could be no doubt to anyone who studied the evidence; and if the prejudice against it was ever to be removed, the medical officers of the Territorial Army were in a better position to effect it than any other body of men in the country.

Sanitary Intelligence.

This was a matter in which not only the medical officers of the Territorial Army could help, but in which all the country practitioners of the British Isles could take a share. The information needed would comprise the situation and character of the best camp grounds, the nature of the water supplies of the county, and the buildings suitable for adaptation as barracks and hospitals and the local facilities for procuring the equipment necessary for such adaptation.

National Physical Education.

There was no doubt that ordinary men of the class from which the ranks of the regular army were recruited, and to a less extent, though still to a certain extent, the classes from which the rank and file of the Territorial Army would be drawn, suffered from a want of ability to get the best use out of their limbs. This could only be remedied by universal physical education in boyhood and youth.

Lieutenant-Colonel C. P. OLIVER, R.A.M.C.(T.F.), remarked that he had lately had personal experience of the light and airy fashion in which combatant officers of the Territorial Force treated the subject, and of the general apathy that pervaded the commissioned ranks in matters of sanitation. He felt convinced that there was a splendid opportunity for the Territorial medical officer to educate and also to gain the sympathy of the combatant officers in this direction. As to the physical deterioration of the recruit, he looked for a great improvement in the physique of the rising generation as a direct result of the medical inspection of children attending the public elementary schools. This was the class from which practically the whole of the recruits were drawn.

Lieutenant-Colonel J. HARPER, R.A.M.C.(T.F.), said the lecturer had pointed out the fundamental hygienic importance of the individual attending to his own excreta. The practical difficulty was how to teach the lesson to the officers and men of the combatant branches, who were the majority of the whole force, and were careless, probably through ignorance, on this point. As regards inoculation for enteric, inasmuch as the protective effect was only temporary, at which period of his service did the lecturer propose that the Territorial soldier should be inoculated so as to be ready for a war the date of which was uncertain?

Colonel ANDREW CLARK, R.A.M.C.(T.F.), mentioned the difficulty medical officers had in showing the combatant officer the necessity for sanitary care. He did not think combatant officers had hitherto really paid attention to the medical department of the volunteer army, but they had to see differently now, and he thought they were proceeding to do better with the point of sanitation.

Major W. S. HARRISON, R.A.M.C.(T.F.), said that as regards inoculation against enteric fever he thought they could safely say that the protection offered by inoculation would last at least two years, and, as a matter of fact, after examining the blood of men who had been inoculated seven years ago, he found traces of the result of their inoculation. He thought that if an army went into the field without being inoculated the amount of enteric would be very much higher than if it was inoculated.

Colonel W. G. MACPHERSON, R.A.M.C., said that military medical officers knew a great deal about camp sanitation, and the education was quite simple: there ought to be no difficulty in training the Territorial Force in the subject. Camp sanitation would not be the chief difficulty in this country. In case of war large standing camps would be avoided, and buildings would probably be the method of accommodating the Territorial Force.

Surgeon-General W. L. GUBBINS said there were three points: First, the inoculation of Territorials; secondly, the collection of statistics as regards camps; thirdly, their education and physical training. Regarding the inoculation of Territorials, he looked upon this as impracticable to begin with. In India, where he had spent the last five years, he often found much difficulty in pushing inoculation, though where there was a good commanding officer possibly some 75 per cent. of the regiment would be inoculated.

Lieutenant-Colonel J. COTTELL, R.A.M.C., alluded to the very excellent remarks as to drinking, and was of opinion that a man could march just as well for half a day without drink as he could with it. He did not think the men should be allowed much drink before they started the day, as it only caused increased thirst.

Major J. K. RITCHIE, R.A.M.C., thought that the education of the officers and men in the elements of sanitation was the most important duty of the Territorial medical officers. He also suggested that during route marches no water bottles should be carried and no men allowed to fall out to drink. They would soon learn how easy it was to do without drinking and how much better they would march.

Lieutenant-Colonel MELVILLE replied briefly.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.—At a meeting on March 3rd, Dr. EDWIN BRAMWELL, in a paper on the *Problem of the sane epileptic*, said that, according to the Poor Law, sane epileptics were epileptics not certified as lunatics under the Lunacy Act of 1890. The Royal Commission on the Care and Control of the Feeble-minded pointed out in their report (1908) that

sane epileptics include epileptics whose minds are feeble, but who will attend to advice; and praise or blame affects them; who are subject to control by friends or self-control.

The school education of the epileptic was often interfered with in such a way as to prejudice his chance in the competition of after-life. Difficulties arose when he left school. He was debarred from following certain occupations in the pursuit of which the occurrence of a fit might, from the special nature of his work, be attended with dangerous consequences. Again, even if he was endowed with the necessary mental and physical qualifications of the successful breadwinner, he was frequently precluded from earning the support necessary for his maintenance by the very fact that he suffered from this disease. It was still more difficult for the sane epileptic of under average mental capacity to support himself in any walk of life other than the lowest form of manual labour. A certain proportion of sane epileptics drifted into the workhouse. For instance, it was ascertained by the special investigator of the Royal Commission that there were 91 individuals whom he regarded as sane epileptics in the workhouses of the Manchester, Chorlton, and Prestwich area.

The great majority of which, all except thirteen, have been obliged to come to the workhouse as the result of the interference with their power of getting or retaining work which the fits entailed. Several had held fairly good positions and done distinctly skilled work before their affliction forced them to relinquish their work.

The speaker urged that the sane epileptic, especially one capable of and willing to work, was at least as deserving a subject of philanthropy as, for instance, the imbecile; yet, to use the words of Dr. Aldren Turner:

Unless he becomes insane, or is at the outset feeble-minded or defective, or becomes a pauper, neither philanthropy nor the State takes note of his condition.

The Royal Commission came to the conclusion that the proportion of sane epileptics in England might be stated at 1 to 1,000 of the total population. It was noted in the Blue Book that "there were no sufficient statistics of sane epileptics in Scotland." So far as the speaker knew, epilepsy was not less frequent north of the Tweed. He

had notes of between 60 and 70 cases of idiopathic epilepsy, the very great majority of which he would class as sane epileptics, and a number of which showed little or no mental deterioration, which he had seen in the out-patient room of Leith Hospital alone during the past six years. These cases were almost without exception resident in the town of Leith. It was rather remarkable that in Scotland, where the hospitals, asylums, deaf and dumb and similar institutions were rightly regarded with so much pride, nothing had been done for epileptics. The only explanation for this circumstance was that up to the present there had been no attempt to point out this deficiency by those who were in the way of seeing a large number of these cases. An epileptic colony in Scotland on the lines of the Chalfont Colony for the reception of epileptics belonging to the respectable working classes and lower middle classes is greatly to be desired. It would require to be founded by private enterprise, and the purpose of the paper was to emphasize the need for provision for such cases, in order that if the opinion of any of the profession was asked regarding the distribution of charitable bequests, they might realize the demand that exists for an institution of this kind. In the discussion which followed, the PRESIDENT, and Drs. AFFLECK, BYRON BRAMWELL, and BURN-MURDOCH and others took part.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—At a meeting held on February 19th, Dr. ROBERT JARDINE in the chair, Sir GEORGE T. BEATSON opened a discussion on the *Treatment of suppurative appendicitis*. He said suppurative appendicitis was localized or diffuse, the latter comparatively rare. General peritonitis was not necessarily suppurative. It might be merely a sympathetic reaction of the unattacked portion of the peritoneum induced by the localized affection in the right iliac region. The intensity of symptoms was no reliable guide to the severity of local conditions. Pathological examination of diseased appendices by Professor Muir demonstrated that the initial mischief was not a general mucous catarrh, but a small lesion in the mucous membrane, by which infection had entered and made its way through all the coats of the appendix. He treated general suppurative peritonitis by rapid laparotomy with drainage rather than by flushing out or wiping out the abdomen. Continual rectal injections of saline were of great importance. In treating localized peritonitis, whether suppurative or not, peristalsis was to be arrested. It hindered the localizing of the inflammation. Thus all laxatives were to be avoided, a semi-starvation diet (albumen water), and an opiate (in the form of Dover's powder) given. Enemata were sufficient for evacuation of the bowels. Light poultices and the Fowler position should be used. Until acute symptoms had subsided this line of treatment should be carried out, and surgical interference not entertained unless the abscess point or other clear indication developed. When abscess formed time should be given for the formation of adhesions to the parietal peritoneum or for the pus, as invariably happened, to lose its virulence. Taking the statistics of the Western Infirmary for ten years: Between 1898 and 1907, cases of appendicitis, 1,007; cured, 869; died, 118; mortality, 11.7 per cent. Sir George Beatson was responsible for 147, of which 141 were treated by the expectant method and operated on afterwards by the interval operation. These 141 all recovered; 6 died, 2 without operation, giving a mortality of 4 per cent. Deducting his cases from the others, 860 cases were treated by the other surgeons. Of these 860, 748 were cured and 112 died, showing a mortality of 13 per cent. The statistics of the Glasgow Royal Infirmary gave an even higher mortality. He pointed out that perforation and gangrene of the appendix did not of themselves justify operation unless accompanied by general suppurative peritonitis, by no means a necessary sequela. Dr. T. K. DALZIEL described the ideal appendix as funnel shaped. This condition generally obtained in children, but, especially towards puberty, the development of the muscular tissue of the colon, together with the usual fold of mucous membrane, tended to cause an abnormal contraction, whereby secretion was retained. This explained the relative infrequency of appendicitis in children and its frequency at puberty. This increased tension

would either cause the obstruction to yield or a series of pathological changes would be set up which usually led to suppuration. He classified suppurative appendicitis as follows:

1. Suppurative catarrh, generally with inflammation of the walls and some fibrinous peritonitis, the cavity of the organ distended with pus.

2. Intramural, with small discrete abscesses scattered through the tissue.

3. Abscess round the appendix shut off by adhesions. The locality of the organ and previous attacks favoured the formation of adhesion. The constitutional disturbance might be remarkably slight. The abscess might burst into the peritoneum, the bladder, the ureter, or faecal fistula. The usual route was fortunately into the intestine. Such cases had prolonged convalescence and frequent recurrences. Another rarer danger was septic thrombo-phlebitis followed by septicæmia and pyæmia. During the past three years Dr. Dalziel had six deaths following localized abscess; in no case had death been due to peritonitis following operation.

4. General suppurative peritonitis. Prognosis could be best made from the pulse and from the general facies. The issue largely depended on the organism present. Streptococcal infection was usually fatal. Infection by *Bacillus coli* was hopeful, mixed infection with *Bacillus coli communis* and staphylococci was intermediate, and was frequently followed by delayed secondary localized abscesses.

5. Suppuration in the lymphatic glands, infection from appendix a rare condition. Complications result from bursting of the glands.

Regarding treatment, there was no question in the cases where pus was confined to the cavity of the appendix. Immediate excision was the only safe course. Immediate operation in suppurative peritonitis was also demanded. When abscess had formed, apparently localized, it might sometimes be left till adhesions had formed, but there was a considerable danger of general peritonitis, thrombo-phlebitis, septicæmia, injury to internal organs, and the removal of the appendix was more difficult, and so recurrences might take place. Pus, he thought, should be evacuated as early as possible, and, with care, the peritoneal cavity could be quite well protected. He made a fairly free incision, carefully protected the peritoneal cavity with gauze, and carefully swabbed out any remaining pus, concretions, or dead tissue. If necessary, the wound should be packed with gauze for four days. Regarding the statistics quoted by Sir George Beaton, there had been no mention of the stage of the disease. Probably many were cases of general septic peritonitis, the hospitals being the dumping ground for dying appendix cases. Dr. DONALD MAC PEARL said that appendicitis from the point of view of the hospital surgeon, who wrote about the disease, would appear to be an entirely different disease from appendicitis as it was met with in practice. To the former it was a dangerous and deadly disease, calling for prompt and heroic measures; to the latter, it was a very manageable ailment. The truth probably lay between these opposing views. During twenty-seven years of general practice he had had many cases of appendicitis. None had been operated on and none had died. No case should be treated light-heartedly. He had frequently seen cases—which he had regretfully left without surgical interference, because under the circumstances that was impossible—give very satisfactory results. Some would insist that opium should never be given. He thought this cruel, and provided it was given merely to diminish suffering, not to narcotize, it was not harmful. He gave small and frequent doses of liq. morph. with tincture of belladonna, combined with mag. sulph. also in small doses. The latter kept the bowel and its contents in a more healthy condition, preventing stasis and the formation of scybala, by encouraging both secretions and peristalsis within safe and beneficial limits. With Sir George Benson, he deprecated too much zeal and haste in operating, and thought that many cases would get well without even delayed operation. Mr. MAYNARD advocated early operation, provided all precautions were taken to protect the general peritoneal cavity. After opening the abdomen he carefully packed off the surrounding parts, wiping away the pus with pledgets of gauze as it oozed from its cavity, until the latter was quite dry; he sought for and removed the appendix, freely swabbed out the pus cavity with pure carbolic acid, dusted copiously with pure iodoform, and finally stuffed and drained. He emphasized the importance of thoroughly removing all pus before attempting to break down adhesions to liberate

the appendix. Early removal in all cases of acute appendicitis should be the usual practice, and they would then never hear of appendicitis with abscess. Dr. RENTON and Dr. KNOX also advocated early operation. Mr. PRINOLZ thought the time element was of great importance, and was another point in favour of early operation. He had found vaccine treatment useful in diminishing infection. Opium should not be used unless an operating surgeon was not available.
